#### Abstract

We study the distribution of 2-Selmer ranks in the family of quadratic twists of an elliptic curve $E$ over an arbitrary number field $K$. Under the assumption that $\operatorname{Gal}(K(E[2]) / K) \cong S_{3}$, we show that the density (counted in a nonstandard way) of twists with Selmer rank $r$ exists for all positive integers $r$, and is given via an equilibrium distribution, depending only on a single parameter (the 'disparity'), of a certain Markov process that is itself independent of $E$ and $K$. More generally, our results also apply to $p$-Selmer ranks of twists of two-dimensional self-dual $\mathbf{F}_{p}$-representations of the absolute Galois group of $K$ by characters of order $p$.

## Introduction

There has been much recent interest in the arithmetic statistics related to the class of all elliptic curves over a given number field. For example, there are the spectacular results due to Bhargava and Shankar [BS10a, BS10b] over $\mathbf{Q}$. There are also precise and extensive statistical conjectures

[^0]
## Z. Klagsbrun, B. Mazur and K. Rubin

(cf. [BKLPR13, PR12]) proposing that density distributions of ranks of $p$-Selmer groups are given by equilibrium distributions arising from certain Markov processes.

This paper deals with the statistical shape of the ranks of 2-Selmer groups in the family of quadratic twists of a given elliptic curve $E$ over a given number field $K$ (that is, twists of $E$ by all quadratic characters of $K$ ).

Define the disparity $\delta(E / K)$ of such a family to be the difference between $1 / 2$ and the density of the members with even 2-Selmer rank. We showed in [KMR13, Theorem 7.6] that when one orders the members of such a quadratic twist family in a certain natural way, this disparity (i.e. such a 'density') exists, and we gave an example of a curve $E$ such that, as $K$ varies, the disparity takes on a dense set of values in its allowable range $\left[-\frac{1}{2}, \frac{1}{2}\right]$. (On the other hand, when $K=\mathbf{Q}$ the disparity is always zero.) Conjecturally, then, this would also imply the same facts for Mordell-Weil ranks of the members of these families.

## Our main result

This paper is a sequel to [KMR13]. We prove the following theorem.
Theorem A. Let $E$ be an elliptic curve over a number field $K$ with

$$
\operatorname{Gal}(K(E[2]) / K) \cong S_{3} .
$$

For every $m \geqslant 0$ and $X>0$ let $m \mapsto \mathcal{B}_{m}(X)=\bigcup_{k} \mathcal{B}_{m, k, X}$ be the 'fan structure' of collections of quadratic characters of $K$ as in Corollary 11.12. Then for every $r \geqslant 0$,

$$
\lim _{m \rightarrow \infty} \lim _{X \rightarrow \infty} \frac{\left|\left\{\chi \in \mathcal{B}_{m}(X): \operatorname{dim}_{\mathbf{F}_{2}} \operatorname{Sel}_{2}\left(E^{\chi} / K\right)=r\right\}\right|}{\left|\mathcal{B}_{m}(X)\right|}= \begin{cases}\left(\frac{1}{2}+\delta(E / K)\right) c_{r} & \text { if } r \text { is odd, } \\ \left(\frac{1}{2}-\delta(E / K)\right) c_{r} & \text { if } r \text { is even }\end{cases}
$$

where $c_{r}$ is the positive real number given by Definition 2.2 with $p=2$.
In other words, the only parameter needed to fully describe the distribution of 2-Selmer ranks in the family of quadratic twists of $E$ (at least in the case when $\operatorname{Gal}(K(E[2]) / K) \cong S_{3}$ ) is the disparity $\delta(E / K)$. A similar result, with the same constants $c_{r}$ (but where the disparity $\delta(E / K)$ is necessarily 0) was obtained by Swinnerton-Dyer [Swi08] in the case where the number field was $\mathbf{Q}$ and the Galois action on 2-torsion was trivial.

## Fan structure

In $\S 3$ below we define the set of levels $\mathcal{D}$ (eventually associated to quadratic characters) for the field $K$ and we axiomatize an assignment of subsets

$$
(m, k, X) \mapsto \mathcal{D}_{m, k, X} \subset \mathcal{D}
$$

for triples $(m, k, X)$ (for integers $m, k \geqslant 0$ and positive real values $X$ ) called a fan structure on $\mathcal{D}$. We consider subsets, $\mathcal{B}_{m, k, X}$, of the group of quadratic characters over $K$ related (according to a certain cuisine) to the $\mathcal{D}_{m, k, X}$. We study average 2 -Selmer ranks of twists of $E$, where we twist by collections of quadratic characters of the form $\mathcal{B}_{m}(X)=\bigcup_{k} \mathcal{B}_{m, k, X}$. See $\S 11$, especially Definition 11.4 and Corollary 11.12, below. The reason for the adjective 'fan' is that the subscript $m$ refers to the number of ramified prime divisors in the twisting characters and, as $m$ increases, our method requires us to average over characters divisible by primes of larger and larger norms. The successive primes are allowed to 'fan out', so to speak, being subject to increasing upper bounds for the absolute value of their norms, this increase being dictated inductively by effective Cebotarev estimates.

## A Markov model for Selmer ranks in families of twists

## On the ordering of twists

Perhaps the most natural order of all elliptic curves over a given number field is via the size of the absolute value of the conductor of the elliptic curve. In the special context of Swinnerton-Dyer's theorem [Swi08] it is a result of Kane [Kan13] (see also [Hea94]) that one obtains the same arithmetic statistics if one orders twists in this manner, rather than ordering them the way Swinnerton-Dyer does. Specifically the disparity (which remains 0 in this context) and the numbers $c_{r}$ are the same as in Swinnerton-Dyer's original theorem.

Something different happens in our more general context. If one orders quadratic twists by the norm of their conductor, rather than by the largest norm of any prime dividing the conductor, the disparity may very well change (see [KMR13, Example 7.13]). It is conceivable, however, that the relative 2 -Selmer rank densities still exist and are as dictated by the (appropriately changed) disparity and the same numbers $c_{r}$ as above.

## Average Mordell-Weil rank

Since the 2-Selmer rank is an upper bound for the Mordell-Weil rank, Theorem A has the following immediate corollary.

Corollary B. Suppose $E$ is an elliptic curve over a number field $K$, and $\operatorname{Gal}(K(E[2]) / K) \cong S_{3}$. With notation as in Theorem A, the average rank of the twists of $E$ satisfies

$$
\lim _{m \rightarrow \infty} \lim _{X \rightarrow \infty} \frac{\sum_{\chi \in \mathcal{B}_{m}(X)} \operatorname{rk}\left(E^{\chi}(K)\right)}{\left|\mathcal{B}_{m}(X)\right|}<1.2646+0.1211 \cdot \delta(E / K)<1.3252
$$

## How generally are these densities Markovian?

A future project is to understand the extent to which Markov models suffice to explain phenomena in contexts of greater generality than we treat here.

For example, considering the four different possible types of images of the Galois group in $\operatorname{Aut}(E[2]) \cong S_{3}$, one expects that each case has its interesting story. For the case when the image is of order 2, see the forthcoming work of the first author [Kla12].

One would also want to see this project extended to deal with abelian varieties of general dimension. A few lucky accidents, however, happen in dimension 1 that allow us to prove our theorem. To explain these accidents we briefly sketch our method.

The 2-Selmer group of an elliptic curve $E$ over a number field $K$ is given by imposing 'local conditions' at every place $v$ of $K$, and restricting to the subgroup of $H^{1}\left(G_{K}, E[2]\right)$ consisting of cohomology classes that satisfy those local conditions at all places. Twisting $E$ by a quadratic character $\chi$ of $K$ does not change the $\mathbf{F}_{2}\left[G_{K}\right]$-module $E[2]$, but can (and usually does) change some of the local conditions. It is natural, when studying statistics of the $\mathbf{F}_{2}$-dimensions of the Selmer groups of these twisted elliptic curves $E^{\chi}$, to first consider the statistics of a larger collection of objects, namely of the subspaces of $H^{1}\left(G_{K}, E[2]\right)$ subject to what we call an arbitrary Selmer structure; namely, where for a given finite set of places $S$ containing all places dividing $2 \infty$ and all places of bad reduction for $E$ we impose what one might call 'incoherent' local conditions on the cohomology groups $H^{1}\left(G_{K_{v}}, E[2]\right)$ by twisting by local quadratic characters $\chi_{v}$ for $v \in S$, retaining the natural local condition at all other places. Such a collection of local quadratic characters $\left\{\chi_{v}\right\}_{v \in S}$ may or may not be 'coherent' in the sense that the package $\left\{\chi_{v}\right\}_{v \in S}$ comes (by restriction) from a single global quadratic character unramified outside $S$. Our method consists in understanding how ranks of these incoherent 2-Selmer groups change as we twist by one local character $\chi_{v}$ at a time. Our Markov process is precisely this successive twisting.

## Z. Klagsbrun, B. Mazur and K. Rubin

The way we pass from statistics regarding this large class of incoherent Selmer structures to those that have global meaning uses what we might call 'free' places $v$. A free place $v$ is one where twisting by $\chi_{v}$ does not change the local Selmer condition, and hence does not change the 2-Selmer rank. The assumption that $E(K)$ has no points of order 2 guarantees that there are enough free places so that every incoherent package of local quadratic characters can be augmented by an appropriate assortment of characters at free places to render the augmented collection coherent, without changing the 2-Selmer rank. Roughly speaking, averaging over the free places allows us to convert rank statistics for incoherent 2-Selmer groups to rank statistics for 2 -Selmer groups of quadratic twists of elliptic curves.

Suppose now that $A$ is a principally polarized abelian variety of dimension $g$, and $v \nmid 2 \infty$ is a prime of good reduction. Then the local cohomology group $H^{1}\left(G_{K_{v}}, A[2]\right)$ is a quadratic space of dimension $2 d$, where $0 \leqslant d \leqslant 2 g$. The local Selmer condition for the twist of $A$ by $\chi_{v}$ is a Lagrangian subspace of $H^{1}\left(G_{K_{v}}, A[2]\right)$. There is a canonical Lagrangian subspace $V_{\mathrm{ur}}$, the unramified space, which is the local condition if $\chi_{v}$ is unramified. If $\chi_{v}$ is ramified, then the local condition is a Lagrangian subspace whose intersection with $V_{\mathrm{ur}}$ is zero. A calculation of Poonen and Rains [PR12, Proposition 2.6] shows that there are $2^{d(d-1) / 2}$ such spaces.

When $d=0$, all the local conditions are necessarily zero, so the 2 -Selmer group is independent of $\chi_{v}$; these are exactly the free places discussed above. When $d=1$, there is only one possibility for the local condition when $\chi_{v}$ is ramified. When $d=2$, there are two possibilities, and one can show that these correspond to the two ramified characters $\chi_{v}$. We do not know which ramified character corresponds to which Lagrangian, but since we are averaging over all the local characters, we do not need to. If $A$ is elliptic curve, then $d \leqslant 2$, so this covers all cases.

However, if $g>1$, then $d$ can be greater than 2. In that case there are more than two possible ramified Lagrangians, but only two ramified local characters. Thus without additional information in this higher-dimensional case, we do not know how to average the Selmer rank over the local characters.

## How generally are densities determined by Cebotarev conditions?

It seems likely that the finer question of how the Selmer rank changes under twist by a single ramified character is not determined by Cebotarev conditions alone! See [FIMR13, § 10].

## Is an elliptic curve determined (up to isogeny) by the Selmer ranks of its twists?

Theorem A shows that the distribution of 2-Selmer ranks is independent of the elliptic curve $E$ over $\mathbf{Q}$, and over a general number field depends only on a single parameter, the disparity. This leads one to ask how much the actual function $\chi \mapsto \operatorname{dim}_{\mathbf{F}_{2}} \operatorname{Sel}_{2}\left(E^{\chi}\right)$ determines about $E$. For example, how often do the rank functions of two nonisogenous elliptic curves coincide? The answer seems to be: sometimes, but not often. For a discussion of this question, some sufficient conditions for nonisogenous elliptic curves to share the same rank function, and some examples, see [MR].

## The layout of the paper

Although our main interest is 2-Selmer ranks of quadratic twists of elliptic curves, our methods also apply to more general Selmer groups attached to two-dimensional self-dual $\mathbf{F}_{p}\left[G_{K}\right]$-modules, so we work in this generality.

The first part of the paper is purely combinatorial. In $\S 1$ we introduce some notation and very basic facts about probability distributions and Markov processes, and in $\S 2$ we introduce the particular Markov process that will govern our Selmer rank statistics. In § 3 we axiomatize

## A Markov model for Selmer ranks in families of twists

the kind of counting structure that will arise for our families of twists, and in § 4 we prove our basic results (Theorem 4.3 and Corollary 4.6) about averages in this general setting.

The second part of the paper contains all the arithmetic. Section 5 describes the general setup of the Selmer groups we will consider, and $\S 6$ shows how twists of elliptic curves fit into this setup. In § 7 we describe how the Selmer rank changes when we change a single local condition, and in § 10 we use class field theory to show that the average over all local twists (incoherent Selmer structures, in the description above) is the same as the average over twists by global characters. Finally, in § 11, we tie everything together to prove Theorem A and related results.

## Part I. Markov processes and fan structures

## 1. Probability distributions

Definition 1.1. View $\mathbf{Z}_{\geqslant 0}=\{0,1,2, \ldots\}$ as a $\sigma$-finite measure space, with each point $x \in \mathbf{Z}_{\geqslant 0}$ having measure 1. Form the Banach space over $\mathbf{R}$ :

$$
\ell^{1}:=L^{1}\left(\mathbf{Z}_{\geqslant 0}\right)=\left\{\text { set maps } f: \mathbf{Z}_{\geqslant 0} \rightarrow \mathbf{R} \text { such that }\|f\|:=\sum_{n \geqslant 0}|f(n)| \text { converges }\right\} .
$$

Let $W \subset \ell^{1}$ denote the closed convex subspace of densities, or probability distributions,

$$
W:=\left\{f \in \ell^{1}: f(n) \geqslant 0 \text { for all } n \in \mathbf{Z}_{\geqslant 0} \text { and }\|f\|=1\right\} .
$$

A bounded linear operator $M: \ell^{1} \rightarrow \ell^{1}$ is called a Markov operator if $M(W) \subset W$. We can write $M$ as an infinite matrix $\left[m_{r, s}\right]_{r, s \in \mathbf{Z}}^{\geqslant 0} 10$ where, for $f \in \ell^{1}$,

$$
(M(f))(s)=\sum_{r \geqslant 0} m_{r, s} f(r),
$$

with $\left\{m_{r, s}\right\}$ bounded, and then $M$ is a Markov operator if and only if $m_{r, s} \geqslant 0$ for all $r, s \geqslant 0$ and $\sum_{s \geqslant 0} m_{r, s}=1$ for every $r$.
Definition 1.2. If $f \in W$, we define the parity $\rho(f)$ of $f$ by

$$
\rho(f):=\sum_{n \text { odd }} f(n) .
$$

Let $W^{+}, W^{-} \subset W$ be the subsets

$$
\begin{aligned}
& W^{+}:=\{f \in W: f(n)=0 \text { if } n \text { is odd }\}=\{f \in W: \rho(f)=0\}, \\
& W^{-}:=\{f \in W: f(n)=0 \text { if } n \text { is even }\}=\{f \in W: \rho(f)=1\} .
\end{aligned}
$$

We say that a Markov operator $M$ is parity preserving if $m_{r, s}=0$ whenever $r \not \equiv s(\bmod 2)$, and $M$ is parity reversing if $m_{r, s}=0$ whenever $r \equiv s(\bmod 2)$.

Define operators $\pi^{+}, \pi^{-}$on $\ell^{1}, \pi^{+}+\pi^{-}=1$, by

$$
\pi_{r, s}^{+}=\left\{\begin{array}{ll}
1 & \text { if } r=s \text { and } r \text { is even, } \\
0 & \text { otherwise },
\end{array} \pi_{r, s}^{-}= \begin{cases}1 & \text { if } r=s \text { and } r \text { is odd } \\
0 & \text { otherwise }\end{cases}\right.
$$

Lemma 1.3. Suppose that $M$ is a Markov operator and $f \in W$.
(i) If $M$ is parity preserving, then $M\left(W^{ \pm}\right) \subset W^{ \pm}, \rho(M(f))=\rho(f)$, and $M \circ \pi^{ \pm}=\pi^{ \pm} \circ M$.
(ii) If $M$ is parity reversing, then $M\left(W^{ \pm}\right) \subset W^{\mp}, \rho(M(f))=1-\rho(f)$, and $M \circ \pi^{ \pm}=\pi^{\mp} \circ M$.
(iii) $\pi^{+}(f) \in(1-\rho(f)) W^{+}$and $\pi^{-}(f) \in \rho(f) W^{-}$.

Proof. Exercise.

## Z. Klagsbrun, B. Mazur and K. Rubin

## 2. Example: the $\bmod p$ Lagrangian operator $M_{L}$

Fix a prime $p$.
Definition 2.1. Define a bounded operator $M_{L}=\left[m_{r, s}\right]$ on $\ell^{1}$ by

$$
m_{r, s}= \begin{cases}1-p^{-r} & \text { if } s=r-1 \geqslant 0 \\ p^{-r} & \text { if } s=r+1 \geqslant 1 \\ 0 & \text { otherwise }\end{cases}
$$

Then $M_{L}$ is a parity reversing Markov operator, and $M_{L}^{2}$ is a parity preserving Markov operator. We call $M_{L}$ the $\bmod p$ Lagrangian operator.
Definition 2.2. For $n \geqslant 0$ define

$$
c_{n}:=\prod_{j=1}^{\infty}\left(1+p^{-j}\right)^{-1} \prod_{j=1}^{n} \frac{p}{p^{j}-1} .
$$

Define $\mathbf{E}^{+}, \mathbf{E}^{-} \in \ell^{1}$ by

$$
\mathbf{E}^{+}(n):=\left\{\begin{array}{ll}
c_{n} & \text { if } n \text { is even } \\
0 & \text { if } n \text { is odd, }
\end{array} \quad \mathbf{E}^{-}(n):= \begin{cases}0 & \text { if } n \text { is even } \\
c_{n} & \text { if } n \text { is odd }\end{cases}\right.
$$

Lemma 2.3. We have:
(i) $\mathbf{E}^{+} \in W^{+}$and $\mathbf{E}^{-} \in W^{-}$;
(ii) $M_{L}\left(\mathbf{E}^{+}\right)=\mathbf{E}^{-}$and $M_{L}\left(\mathbf{E}^{-}\right)=\mathbf{E}^{+}$;
(iii) $M_{L}^{2}\left(W^{+}\right) \subset W^{+}$and $M_{L}^{2}\left(W^{-}\right) \subset W^{-}$.

Proof. For (i), we only need to show that $\sum_{n} \mathbf{E}^{+}(n)=\sum_{n} \mathbf{E}^{-}(n)=1$. See [PR12, Proposition 2.6], or [Hea94] for the case $p=2$.

It follows directly from the definitions that $M_{L}\left(\mathbf{E}^{+}\right)(n)=0$ if $n$ is even. If $n$ is odd, then, using the fact that $c_{n+1} / c_{n}=p /\left(p^{n+1}-1\right)$, we have

$$
M_{L}\left(\mathbf{E}^{+}\right)(n)=c_{n}\left(\left(1-p^{-1-n}\right) \frac{p}{p^{n+1}-1}+p^{1-n} \frac{p^{n}-1}{p}\right)=c_{n}\left(p^{-n}+\left(1-p^{-n}\right)\right)=c_{n}
$$

Thus $M_{L}\left(\mathbf{E}^{+}\right)=\mathbf{E}^{-}$, and in exactly the same way $M_{L}\left(\mathbf{E}^{-}\right)=\mathbf{E}^{+}$.
The third assertion is clear.
Proposition 2.4. For every $f \in W$,

$$
\begin{aligned}
\lim _{k \rightarrow \infty} M_{L}^{2 k}(f) & =(1-\rho(f)) \mathbf{E}^{+}+\rho(f) \mathbf{E}^{-} \\
\lim _{k \rightarrow \infty} M_{L}^{2 k+1}(f) & =\rho(f) \mathbf{E}^{+}+(1-\rho(f)) \mathbf{E}^{-}
\end{aligned}
$$

In particular, if $\rho(f)=\frac{1}{2}$, then $\lim _{k \rightarrow \infty} M_{L}^{k}(f)=\frac{1}{2} \mathbf{E}^{-}+\frac{1}{2} \mathbf{E}^{+}$.
Proof. By Lemma 2.3(iii), we can view $M_{L}^{2}$ as a Markov process on $\mathbf{Z}_{\geqslant 0}^{\text {even }}$, and by Lemma 2.3(i), $\mathbf{E}^{+} \in W^{+}$is an equilibrium state for this Markov process (i.e. $M_{L}^{2}\left(\mathbf{E}^{+}\right)=\mathbf{E}^{+}$). This Markov process is irreducible and aperiodic on $\mathbf{Z}_{\geqslant 0}^{\text {even }}$ in the sense of [Nor97, ch. 1]. By [Nor97, Theorem 1.8.3], it follows that the equilibrium distribution is unique, and that for every $f \in W^{+}$we have

$$
\lim _{k \rightarrow \infty} M_{L}^{2 k}(f)=\mathbf{E}^{+} .
$$

## A Markov model for Selmer ranks in families of twists

In exactly the same way, $\mathbf{E}^{-} \in W^{-}$is the unique equilibrium state for $M_{L}^{2}$ in $W^{-}$and for every $f \in W^{-}$we have $\lim _{k \rightarrow \infty} M_{L}^{2 k}(f)=\mathbf{E}^{-}$. Now the proposition follows from Lemma 1.3(ii,iii).

Remark 2.5. Our description of Markov processes is limited to Markov operators that act on the set of probability distributions. One can more generally define Markov operators as infinite matrices satisfying the conditions appearing immediately prior to Definition 1.2, that act on arbitrary sequences of nonnegative real numbers.

Some of the techniques we develop here can also be applied to such Markov operators, assuming that the operator under consideration has a unique (up to scalar multiple) equilibrium state. See the forthcoming work of the first author and Valko for an arithmetic application of such a case.

## 3. Axiomatizing the Markovian counting setup

In this section we axiomatize the kind of general argument that we will use to find the distribution of Selmer ranks corresponding to ('incoherent', as discussed in the introduction) twists of an elliptic curve.

Fix an elliptic curve $A$ defined over a number field $K$, and a rational prime $p$. To motivate the definitions below, we illustrate each one by giving its interpretation in the elliptic curve case, i.e. the case of Selmer ranks attached to twists of $A[p]$.

### 3.1 Normed set with linear growth

Definition 3.1. A normed set is a set $S$ together with a real-valued norm function $\mathbf{N}: S \rightarrow \mathbf{R}_{>0}$. If $S$ is a normed set, we define $S(X):=\{s \in S: \mathbf{N}(s)<X\}$, and we say that $S$ has linear growth if for every $\epsilon>0$,

$$
\begin{equation*}
X^{1-\epsilon}<|S(X)|<X^{1+\epsilon} \quad \text { for } X \gg_{\epsilon} 1 . \tag{3.1}
\end{equation*}
$$

The norm provides the fundamental ordering that will allow us to take averages.
Fix a normed set $\mathcal{P}$ with linear growth.
Remark 3.2. In the elliptic curve case, let $\Sigma$ be a finite set of places of $K$ including all Archimedean places, all primes where $A$ has bad reduction, and all primes above $p$. Then $\mathcal{P}$ will be the set of all primes of $K$ not in $\Sigma$, with the usual (absolute) norm function. These primes correspond to 'minimal' twists.

### 3.2 Width

Definition 3.3. By a width function $w: \mathcal{P} \rightarrow \mathbf{Z}_{\geqslant 0}$ we mean a function with finite image $I$, and such that for each $i \in I$, the inverse image $\mathcal{P}_{i}:=w^{-1}(i)$ with the induced norm function $\mathbf{N}$ is a normed set with linear growth.

Fix a width function $w$ on $\mathcal{P}$.
Remark 3.4. In the elliptic curve case, if $\mathfrak{q}$ is a prime in $\mathcal{P}$ we define

$$
w(\mathfrak{q}):= \begin{cases}0 & \text { if } \boldsymbol{\mu}_{p} \notin K_{\mathfrak{q}}^{\times}, \\ \operatorname{dim}_{\mathbf{F}_{p}} A\left(K_{\mathfrak{q}}\right)[p] & \text { if } \boldsymbol{\mu}_{p} \in K_{\mathfrak{q}}^{\times} .\end{cases}
$$

Then $\{2\} \subset I \subset\{0,1,2\}$, and if $i \in I$ then $\mathcal{P}_{i}$ has linear growth by the Cebotarev theorem. The width $w(\mathfrak{q})$ is the largest possible change in Selmer rank when we twist by a local character at $\mathfrak{q}$.

## Z. Klagsbrun, B. Mazur and K. Rubin

### 3.3 Levels

Definition 3.5. A finite subset of $\bigcup_{i>0} \mathcal{P}_{i}=\{q \in \mathcal{P}: w(q)>0\}$ will be called a level. Denote by $\mathcal{D}$ the set of levels, i.e. the set of all finite subsets of $\bigcup_{i>0} \mathcal{P}_{i}$. We extend $w$ and $\mathbf{N}$ from $\mathcal{P}$ to $\mathcal{D}$ by $w(\delta)=\sum_{q \in \delta} w(q)$ and $\mathbf{N}(\delta)=\prod_{q \in \delta} \mathbf{N}(q)$.
Remark 3.6. In the elliptic curve case, the levels correspond to square-free ideals supported on $\mathcal{P}_{1} \cup \mathcal{P}_{2}$. If $\chi$ is a quadratic character of $K$, then the level of $\chi$ is the part of the conductor of $\chi$ supported on $\mathcal{P}_{1} \cup \mathcal{P}_{2}$.

We exclude primes of width zero from the level because twisting by a prime of width zero has no effect on the Selmer group, either because all such characters are unramified (if $\boldsymbol{\mu}_{p} \notin K_{\mathfrak{q}}^{\times}$) or because $H^{1}\left(K_{\mathfrak{q}}, A[p]\right)=0\left(\right.$ if $\left.A\left(K_{v}\right)[p]=0\right)$.

### 3.4 Rank data

Definition 3.7. By rank data on $\mathcal{D}$ we mean a rule that assigns to every level $\delta \in \mathcal{D}$ a finite set $\Omega_{\delta}$, together with the following extra structure:

- a map (called the rank map) rk : $\Omega_{\delta} \rightarrow \mathbf{Z}_{\geqslant 0}$ for every $\delta$;
- a map $\eta_{\delta, q}: \Omega_{\delta \cup\{q\}} \rightarrow \Omega_{\delta}$ for every $\delta \in \mathcal{D}$ and $q \in \mathcal{P}-\delta$, such that all fibers $\eta_{\delta, q}^{-1}(\omega)$ have cardinality independent of $\delta, q$ and $\omega$.

It follows from the second property of Definition 3.7 that if $|\delta|=\left|\delta^{\prime}\right|$ then $\left|\Omega_{\delta}\right|=\left|\Omega_{\delta^{\prime}}\right|$. Fix rank data on $\mathcal{D}$.

Remark 3.8. In the elliptic curve case, for $\delta \in \mathcal{D}$ we set

$$
\Omega_{\delta}=\left\{\omega=\left(\omega_{v}\right) \in \prod_{v \in \Sigma \cup \delta} \operatorname{Hom}\left(K_{v}^{\times}, \boldsymbol{\mu}_{p}\right): \omega_{\mathfrak{q}} \text { is ramified if } \mathfrak{q} \in \delta\right\}
$$

(we say that $\omega_{\mathfrak{q}}$ is ramified if it is nontrivial on $\mathcal{O}_{\mathfrak{q}}^{\times}$, the local units in $K_{\mathfrak{q}}^{\times}$). The rank map is given by $\operatorname{rk}(\omega):=\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}(A[p], \omega)$, where $\operatorname{Sel}(A[p], \omega)$ is the twisted Selmer group given by Definition 5.12 below, and the map $\eta_{\delta, \mathfrak{q}}: \Omega_{\delta \cup\{\mathfrak{q}\}} \rightarrow \Omega_{\delta}$ is the forgetful map that simply drops $\omega_{\mathfrak{q}}$. Since $w(\mathfrak{q})>0$, there are exactly $p^{2}-p$ ramified characters of $K_{\mathfrak{q}}^{\times}$, so all fibers $\eta_{\delta, \mathfrak{q}}^{-1}(\omega)$ have size $p^{2}-p$.

### 3.5 Rank distribution function

Definition 3.9. Given rank data on $\mathcal{D}$, the corresponding rank distribution function is the function $E: \mathcal{D} \rightarrow W$ defined by

$$
E_{\delta}(r)=\frac{\left|\left\{\omega \in \Omega_{\delta}: \operatorname{rk}(\omega)=r\right\}\right|}{\left|\Omega_{\delta}\right|}
$$

for every $r \geqslant 0$. If $B$ is a nonempty finite subset of $\mathcal{D}$, the rank distribution over $B$ is the average of the $E_{\delta}$ over $\delta \in B$, weighted according to the size of $\Omega_{\delta}$ :

$$
E_{B}:=\frac{\sum_{\delta \in B}\left|\Omega_{\delta}\right| E_{\delta}}{\sum_{\delta \in B}\left|\Omega_{\delta}\right|} \in W .
$$

Thus $E_{B}(r)$ is the probability, as $\delta$ ranges through $B$, that $\operatorname{rk}(\delta)=r$. If all $\delta \in B$ have the same cardinality, then all $\Omega_{\delta}$ have the same cardinality, so $E_{B}=\sum_{\delta \in B} E_{\delta} /|B|$.

## A Markov model for Selmer ranks in families of twists

### 3.6 Governing Markov operators

Definition 3.10. Suppose that $M$ is a Markov operator. We say that $M$ governs the rank data $\Omega$ if for every $\delta \in \mathcal{D}$, every $\omega \in \Omega_{\delta}$, every $i \in I$, and every $s \in \mathbf{Z}_{\geqslant 0}$,

$$
\begin{equation*}
\lim _{X \rightarrow \infty} \frac{\sum_{q \in \mathcal{P}_{i}(X)-\delta}\left|\left\{\chi \in \eta_{\delta, q}^{-1}(\omega): \operatorname{rk}(\chi)=s\right\}\right|}{\sum_{q \in \mathcal{P}_{i}(X)-\delta}\left|\eta_{\delta, q}^{-1}(\omega)\right|}=m_{\mathrm{rk}(\omega), s}^{(i)} \tag{3.2}
\end{equation*}
$$

where $M^{i}=\left[m_{r, s}^{(i)}\right]$.
To say that $M$ governs the rank data means essentially that adding a random $q$ affects the rank statistics in the same way as applying the operator $M^{w(q)}$.

Fix a Markov operator $M$ that governs the rank data $\Omega$.
Remark 3.11. In the elliptic curve case, under suitable hypotheses (see (9.1)-(9.3) below) we will show that the rank data described above are governed by the mod $p$ Lagrangian Markov operator of Definition 2.1.

### 3.7 Convergence rates

Definition 3.12. A convergence rate for $(\Omega, M)$ is a nondecreasing function $\mathcal{L}$ from the infinite real interval $[1, \infty)$ to itself such that for every real number $Y \geqslant 1$, every $\delta \in \mathcal{D}$ with $\mathbf{N}(\delta)<Y$, every $\omega \in \Omega_{\delta}$, every $i \in I$, every $s \in \mathbf{Z}_{\geqslant 0}$, and every $X \geqslant \mathcal{L}(Y)$,

$$
\begin{equation*}
\left|\frac{\sum_{q \in \mathcal{P}_{i}(X)-\delta}\left|\left\{\chi \in \eta_{\delta, q}^{-1}(\omega): \operatorname{rk}(\chi)=s\right\}\right|}{\sum_{q \in \mathcal{P}_{i}(X)-\delta}\left|\eta_{\delta, q}^{-1}(\omega)\right|}-m_{\mathrm{rk}(\omega), s}^{(i)}\right| \leqslant \frac{1}{Y} . \tag{3.3}
\end{equation*}
$$

In other words, $\mathcal{L}$ makes effective the rate of convergence in (3.2).
Fix a convergence rate $\mathcal{L}$ for $\left(\Omega, M_{L}\right)$.
Remark 3.13. In the elliptic curve case, we will show (see Theorem 9.5 below) that $M_{L}$ governs the rank data with a convergence rate that comes from an effective version of the Cebotarev theorem.

### 3.8 Stratification of levels

Definition 3.14. Define a sequence of real-valued functions $\left\{L_{n}(Y)\right\}_{n \geqslant 1}$ by

$$
\begin{aligned}
L_{1}(Y) & :=\mathcal{L}(Y), \\
L_{n+1}(Y) & :=\max \left\{\mathcal{L}\left(\prod_{j \leqslant n} L_{j}(Y)\right), Y L_{n}(Y)\right\}, \quad n \geqslant 1 .
\end{aligned}
$$

If $m, k \in \mathbf{Z}_{\geqslant 0}$ and $X \in \mathbf{R}_{>0}$, define the 'fan'

$$
\mathcal{D}_{m, k, X}:=\left\{\delta \in \mathcal{D}: w(\delta)=k \text { and } \delta=\left\{q_{1}, \ldots, q_{m}\right\} \text { with } \mathbf{N}\left(q_{j}\right)<L_{j}(X) \text { for all } j\right\}
$$

Although we suppress it from the notation, $\mathcal{D}_{m, k, X}$ depends on the (fixed) convergence rate $\mathcal{L}$.

## 4. Averages over fan structures

Keep the notation of the previous section, along with the fixed prime $p$, normed set $\mathcal{P}$, width function $w$ with image $I$, rank data $\Omega$, Markov operator $M$ governing $\Omega$, and convergence rate $\mathcal{L}$ for $(\Omega, M)$. In this section we will show how to use all of this information to compute the rank statistics as we average over our 'fan structures' $\mathcal{D}_{m, k, X}$.

If $B \subset \mathcal{D}$ and $C \subset \mathcal{P}$, define

$$
B * C:=\{\delta \cup\{q\}: \delta \in B, q \in C-\delta\} .
$$

## Z. Klagsbrun, B. Mazur and K. Rubin

Remark 4.1. For our application we would like to compute

$$
\lim _{X \rightarrow \infty} E_{\mathcal{D}(X)}
$$

where $\mathcal{D}(X)=\left\{\delta \in \mathcal{D}: \prod_{q \in \delta} \mathbf{N}(q)<X\right\}$. Unfortunately we have not yet been able to do this. Instead, for every level $\delta \in \mathcal{D}$ and $i \in I$, we will show (Proposition 4.2) that

$$
\lim _{X \rightarrow \infty} E_{\{\delta\} * \mathcal{P}_{i}(X)}=M^{i}\left(E_{\{\delta\}}\right) .
$$

Using this, we will show (Theorem 4.3) that for every $m$ and $k$,

$$
\lim _{X \rightarrow \infty} E_{\mathcal{D}_{m, k, X}}=M^{k}\left(E_{\delta_{0}}\right),
$$

where $\delta_{0}=\emptyset \in \mathcal{D}$. If $M=M_{L}$, then taking the limit as $m$ and $k$ go to infinity, we can use Proposition 2.4 to describe the limiting statistics in terms of the equilibrium states of $M_{L}$ (Corollary 4.6).
Proposition 4.2. Suppose that

$$
b:=\sup \left\{\operatorname{rk}(\omega): \omega \in \Omega_{\delta \cup\{q\}}, q \in \mathcal{P}_{i}\right\}<\infty .
$$

Then for every $Y \geqslant 1$, every $\delta \in \mathcal{D}$ with $\mathbf{N}(\delta)<Y$, every $i \in I$, and every $X \geqslant \mathcal{L}(Y)$, we have the following upper bound on the $\ell^{1}$ norm:

$$
\left\|E_{\{\delta\} * \mathcal{P}_{i}(X)}-M^{i}\left(E_{\delta}\right)\right\| \leqslant \frac{b+1}{Y}
$$

Proof. Fix $s \geqslant 0$, and let $d$ be the common value $\left|\eta_{\delta, q}^{-1}(\omega)\right|$ (independent of $\omega \in \Omega_{\delta}$ and $q \in \mathcal{P}_{i}$ ). Then

$$
\begin{aligned}
E_{\{\delta\} * \mathcal{P}_{i}(X)}(s) & =\frac{1}{\left|\mathcal{P}_{i}(X)-\delta\right|} \sum_{q \in \mathcal{P}_{i}(X)-\delta} E_{\delta \cup\{q\}}(s) \\
& =\frac{1}{\left|\mathcal{P}_{i}(X)-\delta\right|} \sum_{q \in \mathcal{P}_{i}(X)-\delta} \frac{\left|\left\{\omega \in \Omega_{\delta \cup\{q\}}: \operatorname{rk}(\omega)=s\right\}\right|}{\left|\Omega_{\delta \cup\{q\}}\right|} \\
& =\frac{1}{\left|\mathcal{P}_{i}(X)-\delta\right|} \sum_{q \in \mathcal{P}_{i}(X)-\delta} \frac{\sum_{\omega \in \Omega_{\delta}}\left|\left\{\chi \in \eta_{\delta, q}^{-1}(\omega): \operatorname{rk}(\chi)=s\right\}\right|}{d\left|\Omega_{\delta}\right|} \\
& =\frac{1}{\left|\Omega_{\delta}\right|} \sum_{\omega \in \Omega_{\delta}} \frac{\sum_{q \in \mathcal{P}_{i}(X)-\delta}\left|\left\{\chi \in \eta_{\delta, q}^{-1}(\omega): \operatorname{rk}(\chi)=s\right\}\right|}{d\left|\mathcal{P}_{i}(X)-\delta\right|} .
\end{aligned}
$$

On the other hand,

$$
\begin{equation*}
M^{i}\left(E_{\delta}\right)(s)=\sum_{r \geqslant 0} m_{r, s}^{(i)} \frac{\left|\left\{\omega \in \Omega_{\delta}: \operatorname{rk}(\omega)=r\right\}\right|}{\left|\Omega_{\delta}\right|}=\frac{1}{\left|\Omega_{\delta}\right|} \sum_{\omega \in \Omega_{\delta}} m_{\mathrm{rk}(\omega), s^{*}}^{(i)} \tag{4.1}
\end{equation*}
$$

Using inequality (3.3), we conclude that

$$
\left|E_{\{\delta\} * \mathcal{P}_{i}(X)}(s)-M^{i}\left(E_{\delta}\right)(s)\right| \leqslant 1 / Y .
$$

If $s>b$, then $E_{\{\delta\} * \mathcal{P}_{i}(X)}(s)=0$, and by (3.2) we have $m_{\mathrm{rk}(\omega), s}^{(i)}=0$ for every $\omega \in \Omega_{\delta}$. Therefore by (4.1) $M^{i}\left(E_{\delta}\right)(s)=0$ as well. The proposition follows.

## A Markov model for Selmer ranks in families of twists

Theorem 4.3. Suppose that there are constants $b_{0}$, $b_{1}$ such that for every $\delta \in \mathcal{D}$ and every $\omega \in \Omega_{\delta}$,

$$
\operatorname{rk}(\omega) \leqslant b_{1} w(\delta)+b_{0} .
$$

Let $\delta_{0}=\emptyset \in \mathcal{D}$. Then for every $m, k \geqslant 0$ such that $\bigcup_{X} \mathcal{D}_{m, k, X}$ is nonempty,

$$
\lim _{X \rightarrow \infty} E_{\mathcal{D}_{m, k, X}}=M^{k}\left(E_{\delta_{0}}\right) .
$$

Before proving Theorem 4.3, we have the following elementary lemma.
Lemma 4.4. If $B \subset B^{\prime}$ are nonempty finite subsets of $\mathcal{D}$ and all $\delta \in B^{\prime}$ have the same cardinality, then

$$
\left\|E_{B}-E_{B^{\prime}}\right\| \leqslant 2 \frac{\left|B^{\prime}-B\right|}{|B|}
$$

Proof. Let $F=\sum_{\delta \in B} E_{\delta} \in \ell^{1}$ and $G=\sum_{\delta \in B^{\prime}-B} E_{\delta} \in \ell^{1}$. Then

$$
E_{B}-E_{B^{\prime}}=\frac{F}{|B|}-\frac{F+G}{\left|B^{\prime}\right|}=\frac{\left(\left|B^{\prime}\right|-|B|\right) F-|B| G}{|B|\left|B^{\prime}\right|}
$$

so

$$
\left\|E_{B}-E_{B^{\prime}}\right\| \leqslant \frac{\left|B^{\prime}-B\right|}{|B|} \frac{\|F\|}{|B|}+\frac{\|G\|}{\left|B^{\prime}\right|} \leqslant \frac{\left|B^{\prime}-B\right|}{|B|}+\frac{\left|B^{\prime}-B\right|}{|B|} .
$$

Proof of Theorem 4.3. We will prove this by induction on $m$. If $m=0$, then $k=0, \mathcal{D}_{m, k, X}=\left\{\delta_{0}\right\}$ for every $X$, and there is nothing to prove.

Now suppose that $m \geqslant 1$. Define

$$
\mathcal{D}_{m, k, X}^{\prime}:=\left\{\delta \in \mathcal{D}_{m, k, X}: \mathbf{N}(q) \leqslant L_{m-1}(X) \text { for every } q \in \delta\right\},
$$

and for every $i \in I$, let $\mathcal{P}_{i}(X, Y):=\left\{q \in \mathcal{P}_{i}: X \leqslant \mathbf{N}(q)<Y\right\}$ and

$$
B_{i, X}:=\mathcal{D}_{m-1, k-i, X} * \mathcal{P}_{i}\left(L_{m-1}(X), L_{m}(X)\right) .
$$

Then

$$
\begin{equation*}
\mathcal{D}_{m, k, X}=\coprod_{i \in I} B_{i, X} \coprod \mathcal{D}_{m, k, X}^{\prime} . \tag{4.2}
\end{equation*}
$$

If $\delta \in \mathcal{D}_{m-1, k-i}$ then Lemma 4.4 and (3.1) show that for large $X$,

$$
\begin{equation*}
\left\|E_{\{\delta\} * \mathcal{P}_{i}\left(L_{m}(X)\right)}-E_{\{\delta\} * \mathcal{P}_{i}\left(L_{m-1}(X), L_{m}(X)\right)}\right\| \leqslant \frac{2\left|\mathcal{P}_{i}\left(L_{m-1}(X)\right)\right|}{\left|\mathcal{P}_{i}\left(L_{m-1}(X), L_{m}(X)\right)\right|} \tag{4.3}
\end{equation*}
$$

Suppose that $\mathcal{D}_{m-1, k-i, X}$ is nonempty, and abbreviate $D_{X}:=\mathcal{D}_{m-1, k-i, X}$. We will apply Proposition 4.2 with $Y=\prod_{j<m} L_{j}(X)$. For every $\delta \in$ we have $\mathbf{N}(\delta) \leqslant Y$, and $L_{m}(X) \geqslant \mathcal{L}(Y)$. Thus by (4.3) and Proposition 4.2,

$$
\begin{aligned}
\left\|E_{B_{i, X}}-M^{i}\left(E_{D_{X}}\right)\right\| & =\left\|\frac{\sum_{\delta \in D_{X}} E_{\{\delta\} * \mathcal{P}_{i}\left(L_{m-1}(X), L_{m}(X)\right)}}{\left|D_{X}\right|}-\frac{\sum_{\delta \in D_{X}} M^{i}\left(E_{\delta}\right)}{\left|D_{X}\right|}\right\| \\
& \leqslant \frac{\sum_{\delta \in D_{X}}\left\|E_{\{\delta\} * \mathcal{P}_{i}\left(L_{m}(X)\right)}-M^{i}\left(E_{\delta}\right)\right\|}{\left|D_{X}\right|}+\frac{2\left|\mathcal{P}_{i}\left(L_{m-1}(X)\right)\right|}{\left|\mathcal{P}_{i}\left(L_{m-1}(X), L_{m}(X)\right)\right|} \\
& \leqslant \frac{b_{1} k+b_{0}+1}{\prod_{j<m} L_{j}(X)}+\frac{2\left|\mathcal{P}_{i}\left(L_{m-1}(X)\right)\right|}{\left|\mathcal{P}_{i}\left(L_{m-1}(X), L_{m}(X)\right)\right|} .
\end{aligned}
$$

## Z. Klagsbrun, B. Mazur and K. Rubin

Both terms go to zero as $X$ grows (using (3.1) for the second term), and by our induction hypothesis $\lim _{X \rightarrow \infty} E_{D_{X}}=M^{k-i}\left(E_{\delta_{0}}\right)$, so for every $i \in I$,

$$
\begin{equation*}
\lim _{X \rightarrow \infty} E_{B_{i, X}}=M^{k}\left(E_{\delta_{0}}\right) \tag{4.4}
\end{equation*}
$$

By (3.1) we see that for every $\epsilon>0$, as $X$ grows we have

$$
\left|\mathcal{D}_{m, k, X}^{\prime}\right| \ll\left(L_{m-1}(X) \prod_{j<m} L_{j}(X)\right)^{1+\epsilon}
$$

and either $B_{i, X}$ is empty or

$$
\left|B_{i, X}\right| \gg\left(\prod_{j \leqslant m} L_{j}(X)\right)^{1-\epsilon}
$$

In particular, $\lim _{X \rightarrow \infty}\left|\mathcal{D}_{m, k, X}^{\prime}\right| / \sum_{i}\left|B_{i, X}\right|=0$, so by Lemma 4.4 and equations (4.2) and (4.4),

$$
\lim _{X \rightarrow \infty} E_{\mathcal{D}_{m, k, X}}=\lim _{X \rightarrow \infty} E_{\amalg B_{i, X}}=M^{k}\left(E_{\delta_{0}}\right) .
$$

Definition 4.5. Let $\mathcal{D}_{X}^{(k)}=\bigcup_{m} \mathcal{D}_{m, k, X}$.
Note that $\bigcup_{X} \mathcal{D}_{m, k, X}$ is nonempty if and only if $k$ can be written as a sum of $m$ (not necessarily distinct) elements of $I$. In particular, if $\bigcup_{X} \mathcal{D}_{m, k, X}$ is nonempty then $m \leqslant k$, so $\mathcal{D}_{X}^{(k)}$ is finite for every $k$.
Corollary 4.6. Suppose that the hypotheses of Theorem 4.3 hold, and $M=M_{L}$, the $\bmod p$ Lagrangian operator of Definition 2.1. Then

$$
\begin{aligned}
\lim _{k \rightarrow \infty} \lim _{X \rightarrow \infty} E_{\mathcal{D}_{X}^{(2 k)}} & =\left(1-\rho\left(E_{\delta_{0}}\right)\right) \mathbf{E}^{+}+\rho\left(E_{\delta_{0}}\right) \mathbf{E}^{-}, \\
\lim _{k \rightarrow \infty} \lim _{X \rightarrow \infty} E_{\mathcal{D}_{X}^{(2 k+1)}} & =\rho\left(E_{\delta_{0}}\right) \mathbf{E}^{+}+\left(1-\rho\left(E_{\delta_{0}}\right)\right) \mathbf{E}^{-} .
\end{aligned}
$$

where $\mathbf{E}^{+}$and $\mathbf{E}^{-}$are given by Definition 2.2. In particular, these limits depend only on the parity $\rho\left(E_{\delta_{0}}\right)$ of the initial state $E_{\delta_{0}}$. If $\rho\left(E_{\delta_{0}}\right)=1 / 2$, then

$$
\lim _{k \rightarrow \infty} \lim _{X \rightarrow \infty} E_{\mathcal{D}_{X}^{(k)}}=\frac{1}{2} \mathbf{E}^{+}+\frac{1}{2} \mathbf{E}^{-}
$$

Proof. This follows directly from Theorem 4.3 and Proposition 2.4.

## Part II. Application to the distribution of Selmer ranks

## 5. Setup

For the rest of this paper we will apply the results of Part I to study the distribution of Selmer ranks in families of twists.

Fix a number field $K$ and a rational prime $p$. Let $\bar{K}$ denote a fixed algebraic closure of $K$, and $G_{K}:=\operatorname{Gal}(\bar{K} / K)$. Let $\boldsymbol{\mu}_{p}$ denote the group of $p$ th roots of unity in $\bar{K}$. We will use $v$ (respectively, $\mathfrak{q}$ ) for a place (respectively, non-Archimedean place, or prime ideal) of $K$. If $v$ is a place of $K$, we let $K_{v}$ denote the completion of $K$ at $v$, and $K_{v}^{\mathrm{ur}}$ its maximal unramified extension.

## A Markov model for Selmer ranks in families of twists

Fix also a two-dimensional $\mathbf{F}_{p}$-vector space $T$ with a continuous action of $G_{K}$, and with a nondegenerate $G_{K}$-equivariant alternating pairing corresponding to an isomorphism

$$
\begin{equation*}
\wedge^{2} T \xrightarrow{\sim} \boldsymbol{\mu}_{p} \tag{5.1}
\end{equation*}
$$

We say that $T$ is unramified at $v$ if the inertia subgroup of $G_{K_{v}}$ acts trivially on $T$, and in that case we define the unramified subgroup $H_{\mathrm{ur}}^{1}\left(K_{v}, T\right) \subset H^{1}\left(K_{v}, T\right)$ by

$$
H_{\mathrm{ur}}^{1}\left(K_{v}, T\right):=H^{1}\left(K_{v}^{\mathrm{ur}} / K_{v}, T\right)=\operatorname{ker}\left[H^{1}\left(K_{v}, T\right) \rightarrow H^{1}\left(K_{v}^{\mathrm{ur}}, T\right)\right]
$$

If $c \in H^{1}(K, T)$ and $v$ is a place of $K$, we will often abbreviate $c_{v}:=\operatorname{loc}_{v}(c)$ for the localization of $c$ in $H^{1}\left(K_{v}, T\right)$.

We also fix a finite set $\Sigma$ of places of $K$, containing all places where $T$ is ramified, all primes above $p$, and all Archimedean places.
Definition 5.1. If $V$ is a vector space over $\mathbf{F}_{p}$, a quadratic form on $V$ is a function $q: V \rightarrow \mathbf{F}_{p}$ such that:
$-q(a v)=a^{2} q(v)$ for every $a \in \mathbf{F}_{p}$ and $v \in V$;

- the map $(v, w)_{q}:=q(v+w)-q(v)-q(w)$ is a bilinear form.

If $X \subset V$, we denote by $X^{\perp}$ the orthogonal complement of $X$ in $V$ under the pairing $(,)_{q}$. We say that $(V, q)$ is a metabolic space if $(,)_{q}$ is nondegenerate and $V$ has a subspace $X$ such that $X=X^{\perp}$ and $q(X)=0$. Such a subspace $X$ is called a Lagrangian subspace of $V$.

For every place $v$ of $K$, the cup product and the pairing (5.1) induce a pairing

$$
H^{1}\left(K_{v}, T\right) \times H^{1}\left(K_{v}, T\right) \xrightarrow{\cup} H^{2}\left(K_{v}, T \otimes T\right) \longrightarrow H^{2}\left(K_{v}, \boldsymbol{\mu}_{p}\right) .
$$

For every $v$ there is a canonical inclusion $H^{2}\left(K_{v}, \boldsymbol{\mu}_{p}\right) \hookrightarrow \mathbf{F}_{p}$ that is an isomorphism if $v$ is non-Archimedean. The local Tate pairing is the composition

$$
\begin{equation*}
\langle,\rangle_{v}: H^{1}\left(K_{v}, T\right) \times H^{1}\left(K_{v}, T\right) \longrightarrow \mathbf{F}_{p} \tag{5.2}
\end{equation*}
$$

Definition 5.2. Suppose that $v$ is a place of $K$. We say that $q$ is a Tate quadratic form on $H^{1}\left(K_{v}, T\right)$ if the bilinear form induced by $q$ (Definition 5.1) is $\langle,\rangle_{v}$. If $v \notin \Sigma$, then we say that $q$ is unramified if $q(x)=0$ for all $x \in H_{\mathrm{ur}}^{1}\left(K_{v}, T\right)$.
Definition 5.3. Suppose that $T$ is as above. A global metabolic structure $\mathbf{q}$ on $T$ consists of a Tate quadratic form $q_{v}$ on $H^{1}\left(K_{v}, T\right)$ for every place $v$, such that:
(i) $\left(H^{1}\left(K_{v}, T\right), q_{v}\right)$ is a metabolic space for every $v$;
(ii) if $v \notin \Sigma$ then $q_{v}$ is unramified;
(iii) if $c \in H^{1}(K, T)$ then $\sum_{v} q_{v}\left(c_{v}\right)=0$.

Note that if $c \in H^{1}(K, T)$ then $c_{v} \in H_{\mathrm{ur}}^{1}\left(K_{v}, T\right)$ for almost all $v$, so the sum in Definition 5.3(iii) is finite.
Definition 5.4. Suppose that $v$ is a place of $K$ and $q_{v}$ is a quadratic form on $H^{1}\left(K_{v}, T\right)$. Let

$$
\mathcal{H}\left(q_{v}\right):=\left\{\text { Lagrangian subspaces of }\left(H^{1}\left(K_{v}, T\right), q_{v}\right)\right\}
$$

and, if $v \notin \Sigma$,

$$
\mathcal{H}_{\mathrm{ram}}\left(q_{v}\right):=\left\{X \in \mathcal{H}\left(q_{v}\right): X \cap H_{\mathrm{ur}}^{1}\left(K_{v}, T\right)=0\right\} .
$$

## Z. Klagsbrun, B. Mazur and K. Rubin

Lemma 5.5. Suppose that $v \notin \Sigma$ and $q_{v}$ is a Tate quadratic form on $H^{1}\left(K_{v}, T\right)$. Let $d_{v}:=$ $\operatorname{dim}_{\mathbf{F}_{p}} T^{G_{K v}}$. Then:
(i) $\operatorname{dim}_{\mathbf{F}_{p}} H^{1}\left(K_{v}, T\right)=2 d_{v}$;
(ii) every $X \in \mathcal{H}\left(q_{v}\right)$ has dimension $d_{v}$;
(iii) if $d_{v}>0$ and $q_{v}$ is unramified, then $\left|\mathcal{H}_{\mathrm{ram}}\left(q_{v}\right)\right|=p^{d_{v}-1}$.

Proof. [KMR13, Lemma 3.7] (Assertion (iii) follows from [PR12, Proposition 2.6]).
Definition 5.6. Suppose that $T$ is as above and $\mathbf{q}$ is a global metabolic structure on $T$. A Selmer structure $\mathcal{S}$ for $(T, \mathbf{q})$ (or simply for $T$, if $\mathbf{q}$ is understood) consists of:

- a finite set $\Sigma_{\mathcal{S}}$ of places of $K$, containing $\Sigma$;
- for every $v \in \Sigma_{\mathcal{S}}$, a Lagrangian subspace $H_{\mathcal{S}}^{1}\left(K_{v}, T\right) \subset H^{1}\left(K_{v}, T\right)$.

If $\mathcal{S}$ is a Selmer structure, we set $H_{\mathcal{S}}^{1}\left(K_{v}, T\right):=H_{\mathrm{ur}}^{1}\left(K_{v}, T\right)$ if $v \notin \Sigma_{\mathcal{S}}$, and we define the Selmer group $H_{\mathcal{S}}^{1}(K, T) \subset H^{1}(K, T)$ by

$$
H_{\mathcal{S}}^{1}(K, T):=\operatorname{ker}\left(H^{1}(K, T) \longrightarrow \bigoplus_{v} H^{1}\left(K_{v}, T\right) / H_{\mathcal{S}}^{1}\left(K_{v}, T\right)\right)
$$

i.e. the subgroup of $c \in H^{1}(K, T)$ such that $c_{v} \in H_{\mathcal{S}}^{1}\left(K_{v}, T\right)$ for every $v$.

Definition 5.7. If $L$ is a field, define

$$
\mathcal{C}(L):=\operatorname{Hom}\left(G_{L}, \boldsymbol{\mu}_{p}\right)
$$

(throughout this paper, 'Hom' will always mean continuous homomorphisms). If $L$ is a local field, we let $\mathcal{C}_{\text {ram }}(L) \subset \mathcal{C}(L)$ denote the subset of ramified characters. In this case local class field theory identifies $\mathcal{C}(L)$ with $\operatorname{Hom}\left(L^{\times}, \boldsymbol{\mu}_{p}\right)$, and $\mathcal{C}_{\text {ram }}(L)$ is then the subset of characters nontrivial on the local units $\mathcal{O}_{L}^{\times}$. Let $\mathbf{1}_{L} \in \mathcal{C}(L)$ denote the trivial character.

There is a natural action of $\operatorname{Aut}\left(\boldsymbol{\mu}_{p}\right)=\mathbf{F}_{p}^{\times}$on $\mathcal{C}(L)$, and we let $\mathcal{F}(L):=\mathcal{C}(L) / \operatorname{Aut}\left(\boldsymbol{\mu}_{p}\right)$. Then $\mathcal{F}(L)$ is naturally identified with the set of cyclic extensions of $L$ of degree dividing $p$, via the correspondence that sends $\chi \in \mathcal{C}(L)$ to the fixed field $\bar{L}^{\operatorname{ker}(\chi)}$ of $\operatorname{ker}(\chi)$ in $\bar{L}$. If $L$ is a local field, then $\mathcal{F}_{\text {ram }}(L)$ denotes the set of ramified extensions in $\mathcal{F}(L)$.
Definition 5.8. Define

$$
\begin{aligned}
& \mathcal{P}_{i}:=\left\{\mathfrak{q}: \mathfrak{q} \notin \Sigma, \boldsymbol{\mu}_{p} \subset K_{\mathfrak{q}}, \text { and } \operatorname{dim}_{\mathbf{F}_{p}} T^{G_{K_{\mathfrak{q}}}}=i\right\} \quad \text { if } 1 \leqslant i \leqslant 2, \\
& \mathcal{P}_{0}:=\left\{\mathfrak{q}: \mathfrak{q} \notin \Sigma \cup \mathcal{P}_{1} \cup \mathcal{P}_{2}\right\}, \\
& \mathcal{P}:=\mathcal{P}_{0} \amalg \mathcal{P}_{1} \amalg \mathcal{P}_{2}=\{\mathfrak{q}: \mathfrak{q} \notin \Sigma\} .
\end{aligned}
$$

Define the width function $w: \mathcal{P} \rightarrow\{0,1,2\}$ by $w(\mathfrak{q}):=i$ if $\mathfrak{q} \in \mathcal{P}_{i}$.
Let $K(T)$ denote the field of definition of the elements of $T$, i.e. the fixed field in $\bar{K}$ of $\operatorname{ker}\left(G_{K} \rightarrow \operatorname{Aut}(T)\right)$.

Lemma 5.9. Suppose that $\mathfrak{q}$ is a prime of $K, \mathfrak{q} \notin \Sigma$, and let $\operatorname{Frob}_{\mathfrak{q}} \in \operatorname{Gal}(K(T) / K)$ be a Frobenius element for some choice of prime above $\mathfrak{q}$. Then:
(i) $\mathfrak{q} \in \mathcal{P}_{2}$ if and only if Frob $_{\mathfrak{q}}=1$;
(ii) $\mathfrak{q} \in \mathcal{P}_{1}$ if and only if Frob $_{\mathfrak{q}}$ has order exactly $p$;
(iii) $\mathfrak{q} \in \mathcal{P}_{0}$ if and only if $\operatorname{Frob}_{\mathfrak{q}}^{p} \neq 1$.

## A Markov model for Selmer ranks in families of twists

Proof. See [KMR13, Lemma 4.3].
Definition 5.10. Suppose that $T, \Sigma$ are as above, and $\mathbf{q}$ is a global metabolic structure on $T$. By twisting data we mean:
(i) for every $v \in \Sigma$, a (set) map,

$$
\alpha_{v}: \mathcal{C}\left(K_{v}\right) / \operatorname{Aut}\left(\boldsymbol{\mu}_{p}\right)=\mathcal{F}\left(K_{v}\right) \longrightarrow \mathcal{H}\left(q_{v}\right) ;
$$

(ii) for every $v \in \mathcal{P}_{2}$, a bijection,

$$
\alpha_{v}: \mathcal{C}_{\mathrm{ram}}\left(K_{v}\right) / \operatorname{Aut}\left(\boldsymbol{\mu}_{p}\right)=\mathcal{F}_{\mathrm{ram}}\left(K_{v}\right) \longrightarrow \mathcal{H}_{\mathrm{ram}}\left(q_{v}\right) .
$$

Definition 5.11. Let

$$
\mathcal{D}:=\left\{\text { square-free products of primes } \mathfrak{q} \in \mathcal{P}_{1} \cup \mathcal{P}_{2}\right\}
$$

and if $\mathfrak{d} \in \mathcal{D}$ let $\mathfrak{d}_{1}$ (respectively, $\mathfrak{d}_{2}$ ) be the product of all primes dividing $\mathfrak{d}$ that lie in $\mathcal{P}_{1}$ (respectively, $\mathcal{P}_{2}$ ), so $\mathfrak{d}=\mathfrak{d}_{1} \mathfrak{d}_{2}$. For every $\mathfrak{d} \in \mathcal{D}$, define also:
$-w(\mathfrak{d}):=\sum_{\mathfrak{q} \mid \mathfrak{d}} w(\mathfrak{q})=\left|\left\{\mathfrak{q}: \mathfrak{q} \mid \mathfrak{d}_{1}\right\}\right|+2 \cdot\left|\left\{\mathfrak{q}: \mathfrak{q} \mid \mathfrak{d}_{2}\right\}\right|$, the width of $\mathfrak{d}$;
$-\Sigma(\mathfrak{d}):=\Sigma \cup\{\mathfrak{q}: \mathfrak{q} \mid \mathfrak{d}\} \subset \Sigma \cup \mathcal{P}_{1} \cup \mathcal{P}_{2} ;$
$-\Omega_{\mathfrak{D}}:=\prod_{v \in \Sigma} \mathcal{C}\left(K_{v}\right) \times \prod_{\mathfrak{q} \mid \mathfrak{D}} \mathcal{C}_{\text {ram }}\left(K_{\mathfrak{q}}\right) ;$
$-\Omega_{\mathfrak{\mathfrak { d }}}^{S}:=S \times \prod_{\mathfrak{q} \mid \boldsymbol{D}} \mathcal{C}_{\text {ram }}\left(K_{\mathfrak{q}}\right)$ for every subset $S \subset \Omega_{1}=\prod_{v \in \Sigma} \mathcal{C}\left(K_{v}\right)$;
$-\eta_{\mathfrak{o q}, \mathfrak{q}}: \Omega_{\mathfrak{d q}}^{S} \rightarrow \Omega_{\mathfrak{d}}^{S}$ the projection map, if $\mathfrak{d q} \in \mathcal{D}$.
Note that $\mathcal{D}$ can be identified with the set of finite subsets of $\mathcal{P}_{1} \cup \mathcal{P}_{2}$, as in §3.3.
Definition 5.12. Given $T, \mathbf{q}$, and twisting data as in Definition 5.10, we define a Selmer structure $\mathcal{S}(\omega)$ for every $\mathfrak{d} \in \mathcal{D}$ and $\omega=\left(\omega_{v}\right)_{v} \in \Omega_{\mathfrak{d}}$ as follows.

- Let $\Sigma_{\mathcal{S}(\omega)}:=\Sigma(\mathfrak{d})$.
- If $v \in \Sigma$, let $H_{\mathcal{S}(\omega)}^{1}\left(K_{v}, T\right):=\alpha_{v}\left(\omega_{v}\right)$.
- If $v \mid \mathfrak{d}_{1}$, let $H_{\mathcal{S}(\omega)}^{1}\left(K_{v}, T\right)$ be the unique element of $\mathcal{H}_{\mathrm{ram}}\left(q_{v}\right)$.
- If $v \mid \mathfrak{d}_{2}$, let $H_{\mathcal{S}(\omega)}^{1}\left(K_{v}, T\right):=\alpha_{v}\left(\omega_{v}\right) \in \mathcal{H}_{\mathrm{ram}}\left(q_{v}\right)$.

If $\omega \in \Omega_{\mathfrak{D}}$ we will also write $\operatorname{Sel}(T, \omega):=H_{\mathcal{S}(\omega)}^{1}(K, T)$.
Theorem 5.13. Suppose that $\mathfrak{d} \in \mathcal{D}, \omega \in \Omega_{1}$, and $\omega^{\prime} \in \Omega_{\mathfrak{d}}$. Then

$$
\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}(T, \omega)-\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}\left(T, \omega^{\prime}\right) \equiv w(\mathfrak{d})+\sum_{v \in \Sigma} \operatorname{dim}_{\mathbf{F}_{p}} \alpha_{v}\left(\omega_{v}\right) /\left(\alpha_{v}\left(\omega_{v}\right) \cap \alpha_{v}\left(\omega_{v}^{\prime}\right)\right) \quad(\bmod 2) .
$$

Proof. See [KMR13, Theorem 4.11].
Remark 5.14. By Lemma 5.9 and the Cebotarev theorem, $\mathcal{P}_{2}$ is a normed set with linear growth in the sense of Definition 3.1, and the same holds for $\mathcal{P}_{1}$ if $p \mid[K(T): K]$. (If $p \nmid[K(T): K]$ then Lemma 5.9 shows that $\mathcal{P}_{1}$ is empty).

If $\mathfrak{d} \in \mathcal{D}$ and $\omega \in \Omega_{\mathfrak{d}}$, define $\operatorname{rk}(\omega):=\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}(T, \omega)$. For every choice of subset $S \subset \Omega_{1}$, the sets $\left\{\Omega_{\mathfrak{d}}^{S}: \mathfrak{d} \in \mathcal{D}\right\}$, together with the functions rk : $\Omega_{\mathfrak{d}}^{S} \rightarrow \mathbf{Z}_{\geqslant 0}$ and $\eta_{\mathfrak{o}, \mathfrak{q}}$, give rank data on $\mathcal{D}$ as in Definition 3.7 (using Proposition 7.2(i) below).

We will show in $\S 7$ below that the rank data $\Omega^{S}$ are governed (in the sense of Definition 3.10) by the $\bmod p$ Lagrangian Markov operator $M_{L}$ of Definition 2.1. We will then be able to apply Theorem 4.3.

## Z. Klagsbrun, B. Mazur and K. Rubin

## 6. Example: twists of elliptic curves

Fix for this section an elliptic curve $A$ defined over $K$, a prime $p$, and let $T:=A[p]$. We will show that this $T$ comes equipped with the extra structure that we require, and that with an appropriate choice of twisting data, the Selmer $\operatorname{groups} \operatorname{Sel}(A[p], \chi)$ are classical $p$-Selmer groups of twists of $A$.

The module $T=A[p]$ satisfies the hypotheses of $\S 5$, with the pairing (5.1) given by the Weil pairing. Let $\Sigma$ be a finite set of places of $K$ containing all Archimedean places, all places above $p$, and all primes where $A$ has bad reduction. Let $\mathcal{O}$ denote the ring of integers of the cyclotomic field of $p$ th roots of unity, and $\mathfrak{p}$ the (unique) prime of $\mathcal{O}$ above $p$.

If $p>2$, there is a unique global metabolic structure $\mathbf{q}_{A}=\left(q_{A, v}\right)$ on $A[p]$. For general $p$, there is a canonical global metabolic structure $\mathbf{q}_{A}$ on $A[p]$ constructed from the Heisenberg group; see [PR12, §4] or the proof of [KMR13, Lemma 5.2].

We next define twisting data for $\left(A[p], \Sigma, \mathbf{q}_{A}\right)$ in the sense of Definition 5.10.
Definition 6.1. Suppose that $\chi \in \mathcal{C}(K)$ (or $\chi \in \mathcal{C}\left(K_{v}\right)$ ) is nontrivial. If $p=2$ we let $A^{\chi}$ denote the quadratic twist of $A$ by $\chi$ over $K$ (respectively, $K_{v}$ ). For general $p$, let $F$ denote the cyclic extension of $K$ (respectively, $K_{v}$ ) of degree $p$ corresponding to $\chi$, and let $A^{\chi}$ denote the abelian variety denoted $A_{F}$ in [MRS07, Definition 5.1].

Concretely, if $\chi \in \mathcal{C}(K)$ and $\chi \neq \mathbf{1}_{K}$ then $A^{\chi}$ is an abelian variety of dimension $p-1$ over $K$, defined to be the kernel of the canonical map

$$
\operatorname{Res}_{K}^{F}(A) \longrightarrow A
$$

where $\operatorname{Res}_{K}^{F}(A)$ denotes the Weil restriction of scalars of $A$ from $F$ to $K$. The character $\chi$ induces an inclusion $\mathcal{O} \subset \operatorname{End}_{K}\left(A^{\chi}\right)$ (see [MRS07, Theorem 5.5(iv)]). If $\pi$ is a generator of the ideal $\mathfrak{p}$ of $\mathcal{O}$, then we denote by $\operatorname{Sel}_{\pi}\left(A^{\chi} / K\right)$ the usual $\pi$-Selmer group of $A^{\chi} / K$. In particular, when $p=2, \operatorname{Sel}(A[2], \chi)=\operatorname{Sel}_{2}\left(A^{\chi} / K\right)$ is the classical 2-Selmer group of $A^{\chi} / K$.

For $\chi \in \mathcal{C}(K)$, if $p>2$ let $\mathbf{q}_{A \chi}=\left(q_{A \chi}, v\right)$ be the unique global metabolic structure on $A^{\chi}[\mathfrak{p}]$, and if $p=2$ let $\mathbf{q}_{A \times}$ be the canonical global metabolic structure on the elliptic curve $A^{\chi}$.

If $p=2$, then the two definitions above of $A^{\chi}$ agree, with $\mathcal{O}=\mathbf{Z}$, and $\mathfrak{p}=2$.
Lemma 6.2. There is a canonical $G_{K}$-isomorphism $A^{\chi}[\mathfrak{p}] \cong A[p]$, which identifies $q_{A^{\chi}, v}$ with $q_{A, v}$ for every $v$ and every $\chi \in \mathcal{C}\left(K_{v}\right)$.

Proof. See [KMR13, Lemma 5.2].
Definition 6.3. Let $\pi$ denote any generator of the ideal $\mathfrak{p}$ of $\mathcal{O}$. If $v$ is a place of $K$ and $\chi \in \mathcal{C}\left(K_{v}\right)$, define $\alpha_{v}(\chi)$ to be the image of the composition of the Kummer 'division by $\pi$ ' map with the isomorphism of Lemma 6.2(i):

$$
\alpha_{v}(\chi):=\operatorname{image}\left(A^{\chi}\left(K_{v}\right) / \mathfrak{p} A^{\chi}\left(K_{v}\right) \hookrightarrow H^{1}\left(K_{v}, A^{\chi}[\mathfrak{p}]\right) \xrightarrow{\sim} H^{1}\left(K_{v}, A[p]\right)\right) .
$$

Note that $\alpha_{v}(\chi)$ is independent of the choice of generator $\pi$. For every place $v$ and $\chi \in \mathcal{C}\left(K_{v}\right)$, [KMR13, Lemma 5.4] shows that $\alpha_{v}(\chi) \in \mathcal{H}\left(q_{A, v}\right)$.

## Proposition 6.4.

(i) The maps $\alpha_{v}$ of Definition 6.3, for $v \in \Sigma$ and $v \in \mathcal{P}_{2}$, give twisting data as in Definition 5.10.

## A Markov model for Selmer ranks in families of twists

(ii) Suppose that $\chi \in \mathcal{C}(K)$, and let $\mathfrak{d}$ be the part of the conductor of $\chi$ supported on $\mathcal{P}_{1} \cup \mathcal{P}_{2}$. With the twisting data of (i), and any generator $\pi$ of $\mathfrak{p}$, we have

$$
\operatorname{Sel}_{\pi}\left(A^{\chi} / K\right) \cong \operatorname{Sel}(A[p], \omega)
$$

where $\omega=\left(\ldots, \chi_{v}, \ldots\right)_{v \in \Sigma(\mathfrak{d})} \in \Omega_{\mathfrak{d}}$ with $\chi_{v} \in \mathcal{C}\left(K_{v}\right)$ the restriction of $\chi$ to $G_{K_{v}}$.
Proof. See [KMR13, Propositions 5.8 and 5.9].

## 7. Changing Selmer ranks

In this section we study how the Selmer rank changes when we change one local condition, i.e. we study $\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}\left(T, \omega^{\prime}\right)-\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}(T, \omega)$ when $\omega^{\prime} \in \Omega_{\mathfrak{d q}}$ projects to $\omega \in \Omega_{\mathfrak{0}}$. Proposition 7.2 evaluates this difference in terms of the dimension of the $\operatorname{localization~} \operatorname{loc}_{\mathfrak{q}}(\operatorname{Sel}(T, \omega))$, and Proposition 9.4 describes the distribution of the values $\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{loc}_{\mathfrak{q}}(\operatorname{Sel}(T, \omega))$ as $\mathfrak{q}$ varies.

For the rest of this paper we fix $T$ and $\Sigma$ as in $\S 5$, a global metabolic structure $\mathbf{q}$ on $T$ as in Definition 5.3, and twisting data as in Definition 5.10. Recall that $K(T)$ is the field of definition of the elements of $T$, i.e. the fixed field in $\bar{K}$ of $\operatorname{ker}\left(G_{K} \rightarrow \operatorname{Aut}(T)\right)$.

For the rest of this paper we assume also that

$$
\begin{equation*}
\operatorname{Pic}\left(\mathcal{O}_{K, \Sigma}\right)=0 \tag{7.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathcal{O}_{K, \Sigma}^{\times} /\left(\mathcal{O}_{K, \Sigma}^{\times}\right)^{p} \longrightarrow \prod_{v \in \Sigma} K_{v}^{\times} /\left(K_{v}^{\times}\right)^{p} \quad \text { is injective } \tag{7.2}
\end{equation*}
$$

where $\mathcal{O}_{K, \Sigma}$ is the ring of $\Sigma$-integers of $K$, i.e. the elements that are integral at all $\mathfrak{q} \notin \Sigma$. Lemma 6.1 of [KMR13] shows that (7.1) and (7.2) can always be satisfied by enlarging $\Sigma$ if necessary.

Recall the set $\mathcal{D}$, and for $\mathfrak{d} \in \mathcal{D}$ the sets $\Sigma(\mathfrak{d}), \Omega_{\mathfrak{d}}$, and $\mathcal{C}(\mathfrak{d})$, all from Definition 5.11. If $\mathfrak{d} \in \mathcal{D}$ and $\omega \in \Omega_{\mathfrak{d}}$, recall that $\operatorname{rk}(\omega):=\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}(T, \omega)$, and if $\mathfrak{d q} \in \mathcal{D}$, let $\eta_{\mathfrak{d}, \mathfrak{q}}: \Omega_{\mathfrak{d q}} \rightarrow \Omega_{\mathfrak{d}}$ be the natural projection.

Definition 7.1. Suppose that $\mathfrak{d} \in \mathcal{D}$ and $\omega \in \Omega_{\mathfrak{d}}$. If $\mathfrak{q} \in \mathcal{P}_{1} \cup \mathcal{P}_{2}$ and $\mathfrak{q} \nmid \mathfrak{d}$, define

$$
t(\mathfrak{q})=t(\omega, \mathfrak{q}):=\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{image}\left(\operatorname{Sel}(T, \omega) \xrightarrow{\mathrm{loc}_{\mathfrak{q}}} H_{\mathrm{ur}}^{1}\left(K_{\mathfrak{q}}, T\right)\right) .
$$

Proposition 7.2. Suppose that $\mathfrak{d} \in \mathcal{D}, \omega \in \Omega_{\mathfrak{d}}$, and $\mathfrak{q} \in \mathcal{P}_{1} \cup \mathcal{P}_{2}$ and $\mathfrak{q} \nmid \mathfrak{d}$.
(i) We have $\left|\eta_{\mathcal{O}, \mathfrak{q}}^{-1}(\omega)\right|=p(p-1)$.
(ii) Suppose that $\mathfrak{q} \in \mathcal{P}_{1}$ and $\omega^{\prime} \in \eta_{\mathfrak{D}, \mathfrak{q}}^{-1}(\omega) \subset \Omega_{\mathfrak{o q}}$. Then $0 \leqslant t(\mathfrak{q}) \leqslant 1$, and

$$
\operatorname{rk}\left(\omega^{\prime}\right)= \begin{cases}\operatorname{rk}(\omega)-1 & \text { if } t(\mathfrak{q})=1 \\ \operatorname{rk}(\omega)+1 & \text { if } t(\mathfrak{q})=0\end{cases}
$$

(iii) Suppose that $\mathfrak{q} \in \mathcal{P}_{2}$. Then $0 \leqslant t(\mathfrak{q}) \leqslant 2$, and

$$
\operatorname{rk}\left(\omega^{\prime}\right)= \begin{cases}\operatorname{rk}(\omega)-2 & \text { if } t(\mathfrak{q})=2, \text { for every } \omega^{\prime} \in \eta_{\mathfrak{o}, \mathfrak{q}}^{-1}(\omega), \\ \operatorname{rk}(\omega) & \text { if } t(\mathfrak{q})=1, \text { for every } \omega^{\prime} \in \eta_{\mathfrak{o}, \mathfrak{q}}^{-1}(\omega), \\ \operatorname{rk}(\omega)+2 & \text { if } t(\mathfrak{q})=0, \text { for exactly } p-1 \text { of the } \omega^{\prime} \in \eta_{\mathfrak{l}, \mathfrak{q}}^{-1}(\omega), \\ \operatorname{rk}(\omega) & \text { if } t(\mathfrak{q})=0, \text { for all other } \omega^{\prime} \in \eta_{\mathfrak{o}, \mathfrak{q}}^{-1}(\omega) .\end{cases}
$$

## Z. Klagsbrun, B. Mazur and K. Rubin

Proof. For the first assertion we have $\left|\eta_{0, \mathfrak{q}}^{-1}(\omega)\right|=\left|\mathcal{C}_{\mathrm{ram}}\left(K_{\mathfrak{q}}\right)\right|=p(p-1)$.
Let $\mathcal{S}(\omega)$ be the Selmer structure of Definition 5.12. Define

$$
\begin{aligned}
& \operatorname{Sel}(T, \omega)^{(\mathfrak{q})}:=\operatorname{ker}\left(H^{1}(K, T) \xrightarrow{\oplus \operatorname{loc}_{v}} \bigoplus_{v \neq \mathfrak{q}} H^{1}\left(K_{v}, T\right) / H_{\mathcal{S}(\omega)}^{1}\left(K_{v}, T\right)\right), \\
& \operatorname{Sel}(T, \omega)_{(\mathfrak{q})}:=\operatorname{ker}\left(H_{\mathcal{S}(\omega)}^{1}\left(K_{v}, T\right)^{(\mathfrak{q})} \xrightarrow{\operatorname{loc}_{\mathfrak{q}}} H^{1}\left(K_{\mathfrak{q}}, T\right)\right) .
\end{aligned}
$$

Then we have $\operatorname{Sel}(T, \omega)_{(\mathfrak{q})} \subset \operatorname{Sel}(T, \omega) \subset \operatorname{Sel}(T, \omega)^{(\mathfrak{q})}$, and if $\omega^{\prime} \in \eta_{\mathfrak{0}, \mathfrak{q}}^{-1}(\omega)$ then we also have $\operatorname{Sel}(T, \omega)_{(\mathfrak{q})} \subset \operatorname{Sel}\left(T, \omega^{\prime}\right) \subset \operatorname{Sel}(T, \omega)^{(\mathfrak{q})}$.

Let $V:=\operatorname{loc}_{\mathfrak{q}}\left(\operatorname{Sel}(T, \omega)^{(\mathfrak{q})}\right) \subset H^{1}\left(K_{\mathfrak{q}}, T\right)$. Poitou-Tate global duality (see, for example, [Mil86, Theorem I.4.10] or [Tat62, Theorem 3.1]) shows that $V$ is a maximal isotropic subspace of $H^{1}\left(K_{\mathfrak{q}}, T\right)$ with respect to the local Tate pairing, and by Definition 5.3(iii) the quadratic form $q_{\mathfrak{q}}$ vanishes on $V$, so $V \in \mathcal{H}\left(q_{\mathfrak{q}}\right)$. In particular, if $\mathfrak{q} \in \mathcal{P}_{i}$, then by Lemma 5.5,

$$
\operatorname{dim}_{\mathbf{F}_{p}} V=\frac{1}{2} \operatorname{dim}_{\mathbf{F}_{p}} H^{1}\left(K_{\mathfrak{q}}, T\right)=i .
$$

Let $V_{\mathrm{ur}}:=H_{\mathrm{ur}}^{1}\left(K_{\mathfrak{q}}, T\right) \in \mathcal{H}\left(q_{\mathfrak{q}}\right)$, the unramified subspace. Suppose that $\omega^{\prime} \in \eta_{\mathfrak{o}, \mathrm{q}}^{-1}(\omega)$, and let $\omega_{\mathfrak{q}}^{\prime}$ be its $\mathfrak{q}$-component. If $i=1$ let $V_{\omega_{\mathfrak{q}}^{\prime}}$ be the unique element of $\mathcal{H}_{\text {ram }}\left(q_{\mathfrak{q}}\right)$, and if $i=2$ let $V_{\omega_{\mathfrak{q}}^{\prime}}:=\alpha_{\mathfrak{q}}\left(\omega_{\mathfrak{q}}^{\prime}\right)$, where $\alpha_{\mathfrak{q}}: \mathcal{C}\left(K_{\mathfrak{q}}\right) \rightarrow \mathcal{H}_{\text {ram }}\left(q_{\mathfrak{q}}\right)$ is part of the given twisting data. Then by definition we have exact sequences

$$
\begin{gathered}
0 \longrightarrow \operatorname{Sel}(T, \omega)_{\mathfrak{q}} \longrightarrow \operatorname{Sel}(T, \omega) \xrightarrow{\text { loc }_{\mathfrak{q}}} V \cap V_{\mathrm{ur}} \longrightarrow 0, \\
0 \longrightarrow \operatorname{Sel}(T, \omega)_{\mathfrak{q}} \longrightarrow \operatorname{Sel}\left(T, \omega^{\prime}\right) \xrightarrow{\text { loc }_{\mathfrak{q}}} V \cap V_{\omega_{\mathfrak{q}}^{\prime}} \longrightarrow 0,
\end{gathered}
$$

and $t(\mathfrak{q})=\operatorname{dim}_{\mathbf{F}_{p}}\left(V \cap V_{\text {ur }}\right)$. We deduce that

$$
\begin{equation*}
\operatorname{rk}\left(\omega^{\prime}\right)-\operatorname{rk}(\omega)=\operatorname{dim}_{\mathbf{F}_{p}}\left(V \cap V_{\omega_{\mathfrak{q}}^{\prime}}\right)-t(\mathfrak{q}) . \tag{7.3}
\end{equation*}
$$

Suppose first that $\mathfrak{q} \in \mathcal{P}_{1}$, so $i=1$. In this case we have $V \in \mathcal{H}\left(q_{\mathfrak{q}}\right)=\left\{V_{\mathrm{ur}}, V_{\omega_{\mathfrak{q}}^{\prime}}\right\}$, and $\operatorname{dim}_{\mathbf{F}_{p}}\left(V_{\mathrm{ur}}\right)=\operatorname{dim}_{\mathbf{F}_{p}}\left(V_{\omega_{\mathfrak{q}}^{\prime}}\right)=1$. If $V=V_{\text {ur }}$ then $t(\mathfrak{q})=1$ and $V \cap V_{\omega_{\mathfrak{q}}^{\prime}}=0$, and if $V=V_{\omega_{\mathfrak{q}}^{\prime}}$ then $t(\mathfrak{q})=0$ and $V \cap V_{\omega_{\mathfrak{q}}^{\prime}}=V$. Now (ii) follows from (7.3).

Next, suppose that $\mathfrak{q} \in \mathcal{P}_{2}$. By Theorem 5.13 we have $\operatorname{rk}\left(\omega^{\prime}\right) \equiv \operatorname{rk}(\omega)(\bmod 2)$, and by definition $V_{\omega_{\mathrm{q}}^{\prime}} \cap V_{\mathrm{ur}}=0$.

If $t(\mathfrak{q})=2$, then $V=V_{\mathrm{ur}}$, so $V \cap V_{\omega_{\mathfrak{q}}^{\prime}}=0$ and $\operatorname{rk}\left(\omega^{\prime}\right)=\operatorname{rk}(\omega)-2$ by (7.3).
If $t(\mathfrak{q})=1$, then (7.3) shows that $\operatorname{dim}_{\mathbf{F}_{p}}\left(V \cap V_{\omega_{\mathfrak{q}}^{\prime}}\right)$ must be odd. Therefore $\operatorname{dim}_{\mathbf{F}_{p}}\left(V \cap V_{\omega_{\mathfrak{q}}^{\prime}}\right)=1$ and $\operatorname{rk}\left(\omega^{\prime}\right)=\operatorname{rk}(\omega)$.

If $t(\mathfrak{q})=0$, then $V \in \mathcal{H}_{\operatorname{ram}}\left(q_{\mathfrak{q}}\right)$, and (7.3) shows that $\operatorname{dim}_{\mathbf{F}_{p}}\left(V \cap V_{\omega_{\mathfrak{q}}^{\prime}}\right)$ must be even, so $\operatorname{dim}_{\mathbf{F}_{p}}\left(V \cap V_{\omega_{q}^{\prime}}\right)=0$ or 2 . But $\operatorname{dim}_{\mathbf{F}_{p}}\left(V \cap V_{\omega_{q}^{\prime}}\right)=2$ if and only if $V_{\omega_{q}^{\prime}}=V$. Since the twisting data map $\alpha_{\mathfrak{q}}: \mathcal{C}\left(K_{\mathfrak{q}}\right) / \operatorname{Aut}\left(\boldsymbol{\mu}_{p}\right) \rightarrow \mathcal{H}_{\mathrm{ram}}\left(q_{\mathfrak{q}}\right)$ is a bijection, there are exactly $p-1=\left|\operatorname{Aut}\left(\boldsymbol{\mu}_{p}\right)\right|$ characters $\omega_{\mathfrak{q}}^{\prime} \in \mathcal{C}\left(K_{\mathfrak{q}}\right)$ such that $V_{\omega_{\mathfrak{q}}^{\prime}}=V$. Now the last part of (iii) follows from (7.3).

Corollary 7.3. Suppose that $\mathfrak{d} \in \mathcal{D}$ and $\omega \in \Omega_{\mathfrak{d}}$. Then

$$
\operatorname{rk}(\omega) \leqslant w(\mathfrak{d})+\max \left\{\operatorname{rk}(\bar{\omega}): \bar{\omega} \in \Omega_{1}\right\} .
$$

Proof. Let $\eta_{1}: \Omega_{\mathfrak{0}} \rightarrow \Omega_{1}$ be the natural projection. By Proposition 7.2 and induction we have $\operatorname{rk}(\omega) \leqslant \operatorname{rk}\left(\eta_{1}(\omega)\right)+w(\mathfrak{d})$, and the corollary follows.

## A Markov model for Selmer ranks in families of twists

## 8. An effective Cebotarev theorem

Theorem 8.1. There is a nondecreasing function $\mathcal{L}:[1, \infty) \rightarrow[1, \infty)$ such that for:

- every $Y \geqslant 1$,
- every $\mathfrak{d} \in \mathcal{D}$ with $\mathbf{N} \mathfrak{d}<Y$,
- every Galois extension $F$ of $K$ that is abelian of exponent $p$ over $K(T)$, and unramified outside of $\Sigma(\mathfrak{d})$,
- every pair of subsets $S, S^{\prime} \subset \operatorname{Gal}(F / K)$ stable under conjugation, with $S$ nonempty, and
- every $X>\mathcal{L}(Y)$,
we have

$$
\left|\frac{\left|\left\{\mathfrak{q} \notin \Sigma(\mathfrak{d}): \mathbf{N} \mathfrak{q} \leqslant X, \operatorname{Frob}_{\mathfrak{q}}(F / K) \in S^{\prime}\right\}\right|}{\left|\left\{\mathfrak{q} \notin \Sigma(\mathfrak{d}): \mathbf{N} \mathfrak{q} \leqslant X, \operatorname{Frob}_{\mathfrak{q}}(F / K) \in S\right\}\right|}-\frac{\left|S^{\prime}\right|}{|S|}\right| \leqslant \frac{1}{Y}
$$

(and, in particular, $\left\{\mathfrak{q} \notin \Sigma(\mathfrak{d}): \mathbf{N q} \leqslant X, \operatorname{Frob}_{\mathfrak{q}}(F / K) \in S\right\}$ is nonempty).
Proof. This follows from standard effective versions of the Cebotarev theorem (see, for example, [Ser81, § 2, Theorems 2 and 4]) together with the observations that:

- $[F: \mathbf{Q}]$ is bounded by $c_{1} p^{c_{2} w(\mathfrak{d})}$ with constants $c_{1}, c_{2}$ depending only on $K(T)$ and $\Sigma$;
- the absolute discriminant $D_{F}$ of $F$ is bounded by $\mathbf{N} \mathfrak{d}^{[K: \mathbf{Q}]}$ times a constant depending only on $K$ and $\Sigma$;
- the exceptional (Siegel) zeros of $\zeta_{F}(s)$ are bounded away from 1 by a constant depending only on $[F: \mathbf{Q}]$ and $D_{F}$ (see, for example, [Sta74, Lemmas 8 and 11]).

## 9. The governing Markov operator

For the rest of the paper, we suppose that the image of the map $G_{K} \rightarrow \operatorname{Aut}(T)$ is large enough so that the following three properties hold:

$$
\begin{gather*}
T \text { is a simple } G_{K} \text {-module, }  \tag{9.1}\\
\operatorname{Hom}_{G_{K\left(\mu_{p}\right)}}(T, T)=\mathbf{F}_{p},  \tag{9.2}\\
H^{1}(K(T) / K, T)=0 . \tag{9.3}
\end{gather*}
$$

Remark 9.1. For example, (9.1)-(9.3) all hold if the image of the natural map $G_{K} \rightarrow$ $\operatorname{Aut}(T) \cong \mathrm{GL}(T)$ contains $\mathrm{SL}(T)$ or the normalizer of a Cartan subgroup. If $p=2$ then these conditions hold if and only if $\operatorname{Gal}(K(T) / K) \cong S_{3}$.

Definition 9.2. Suppose that $\mathfrak{d} \in \mathcal{D}$ and $\omega \in \Omega_{\mathfrak{D}}$. Let $\operatorname{Res}_{K(T)}$ denote the composition

$$
\begin{equation*}
H^{1}(K, T) \longrightarrow H^{1}(K(T), T)^{\operatorname{Gal}(K(T) / K)}=\operatorname{Hom}\left(G_{K(T)}, T\right)^{\operatorname{Gal}(K(T) / K)} . \tag{9.4}
\end{equation*}
$$

Let $F_{\mathfrak{d}, \omega}$ be the smallest extension of $K(T)$ such that for every $c \in \operatorname{Sel}(T, \omega)$, the homomorphism $\operatorname{Res}_{K(T)} c: G_{K(T)} \rightarrow T$ factors through $\operatorname{Gal}\left(F_{\mathfrak{0}, \omega} / K(T)\right)$. In other words, $F_{\mathfrak{0}, \omega}$ is the fixed field of $\bigcap_{c \in \operatorname{Sel}(T, \omega)} \operatorname{ker}\left(\operatorname{Res}_{K(T)} c\right)$. Then $F_{\mathfrak{d}, \omega}$ is Galois over $K$, and $\operatorname{Gal}(K(T) / K)$ acts on $\operatorname{Gal}\left(F_{\mathfrak{d}, \omega} / K(T)\right)$.
Proposition 9.3. Let $\Gamma:=\operatorname{Gal}(K(T) / K)$. Then for every $\mathfrak{d} \in \mathcal{D}$ and $\omega \in \Omega_{\mathfrak{d}}$ :
(i) there is a $\Gamma$-module isomorphism $\operatorname{Gal}\left(F_{\mathfrak{0}, \omega} / K(T)\right) \cong T^{\mathrm{rk}(\omega)}$;

## Z. Klagsbrun, B. Mazur and K. Rubin

(ii) the map $\operatorname{Res}_{K(T)}: \operatorname{Sel}(T, \omega) \rightarrow \operatorname{Hom}\left(G_{K(T)}, T\right)$ induces isomorphisms

$$
\begin{aligned}
& \operatorname{Sel}(T, \omega) \xrightarrow{\sim} \operatorname{Hom}\left(\operatorname{Gal}\left(F_{\mathfrak{d}, \omega} / K(T)\right), T\right)^{\Gamma}, \\
& \operatorname{Gal}\left(F_{\mathfrak{J}, \omega} / K(T)\right) \xrightarrow{\sim} \operatorname{Hom}(\operatorname{Sel}(T, \omega), T) ;
\end{aligned}
$$

(iii) $F_{\mathfrak{d}, \omega} / K$ is unramified outside of $\Sigma(\mathfrak{d})$.

Proof. Let $r:=\operatorname{rk}(\omega)$. Fix a basis $\left\{c_{1}, \ldots, c_{r}\right\}$ of $\operatorname{Sel}(T, \omega)$ and, for each $i$, let $\tilde{c}_{i}:=\operatorname{Res}_{K(T)} c_{i} \in$ $\operatorname{Hom}\left(G_{K(T)}, T\right)^{\Gamma}$. Then

$$
\begin{equation*}
\tilde{c}_{1} \times \cdots \times \tilde{c}_{r}: \operatorname{Gal}\left(F_{\mathfrak{o}, \omega} / K(T)\right) \longrightarrow T^{r} \tag{9.5}
\end{equation*}
$$

is a $\Gamma$-equivariant injection. Let $W$ be the $\mathbf{F}_{p}[\Gamma]$-module $\operatorname{Gal}\left(F_{\mathfrak{J}, \omega} / K(T)\right)$. Since $W$ is isomorphic to a $\Gamma$-invariant submodule of the semisimple module $T^{r}, W$ is also semisimple. If $U$ is an irreducible constituent of $W$, then $U$ is also an irreducible constituent of $T^{r}$, so $U \cong T$. Therefore $W \cong T^{j}$ for some $j$. Then $\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Hom}(W, T)^{\Gamma}=j$ by our assumption that $\operatorname{Hom}_{G_{K}}(T, T)=\mathbf{F}_{p}$. On the other hand, since $H^{1}(K(T) / K, T)=0$ by (9.3), we have that (9.4) is injective, so $\tilde{c}_{1}, \ldots, \tilde{c}_{r}$ are $\mathbf{F}_{p}$-linearly independent and $\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Hom}(W, T)^{\Gamma} \geqslant r$. Therefore $j=r$, so (9.5) is an isomorphism and (i) holds. The two displayed maps of (ii) are injective by definition, and both sides of the first map (respectively, second map) have order $p^{r}$ (respectively, $p^{2 r}$ ), so both maps are isomorphisms.

By Definition 5.12, every $c \in \operatorname{Sel}(T, \omega)$ is unramified outside of $\Sigma(\mathfrak{d})$, so each $\operatorname{Res}_{K(T)} c$ is unramified outside of $\Sigma(\mathfrak{d})$, so $F_{\mathfrak{d}, \omega} / K$ is unramified outside of $\Sigma(\mathfrak{d})$.

Recall the sets $\mathcal{P}_{1}, \mathcal{P}_{2}$ of Definition 5.8. For $\mathfrak{d} \in \mathcal{D}, \omega \in \Omega_{\mathfrak{d}}$, and $\mathfrak{q} \in \mathcal{P}_{1} \cup \mathcal{P}_{2}$ with $\mathfrak{q} \nmid \mathfrak{d}$, recall that

$$
t(\mathfrak{q})=t(\omega, \mathfrak{q}):=\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{image}\left(\operatorname{Sel}(T, \omega) \xrightarrow{\operatorname{loc}_{\mathfrak{q}}} H_{\mathrm{ur}}^{1}\left(K_{\mathfrak{q}}, T\right)\right)
$$

as in Definition 7.1. In the next proposition we show that $t(\mathfrak{q})$ depends only on the FrobeniusFrob $\mathfrak{q}_{\mathfrak{q}} \in \operatorname{Gal}\left(F_{\mathfrak{0}, \omega} / K\right)$, and, using the Cebotarev theorem, we calculate the density of primes $\mathfrak{q}$ in $\mathcal{P}_{i}$ such that $t(\mathfrak{q})=j$, for each possible pair of values $(i, j)$.
Proposition 9.4. Fix $\mathfrak{d} \in \mathcal{D}$ and $\omega \in \Omega_{\mathfrak{d}}$, and let $c_{i, j}$ be given by the following table:

|  | $j=0$ | $j=1$ | $j=2$ |
| :---: | :---: | :---: | :---: |
| $i=1$ | $p^{-\operatorname{rk}(\omega)}$ | $1-p^{-\operatorname{rk}(\omega)}$ |  |
| $i=2$ | $p^{-2 \operatorname{rk}(\omega)}$ | $(p+1)\left(p^{-\operatorname{rk}(\omega)}-p^{-2 \operatorname{rk}(\omega)}\right)$ | $1-(p+1) p^{-\operatorname{rk}(\omega)}+p^{1-2 \operatorname{rk}(\omega)}$ |

Then for $i=2$ and $j=0,1,2$, we have

$$
\lim _{X \rightarrow \infty} \frac{\left|\left\{\mathfrak{q} \in \mathcal{P}_{i}(X): \mathfrak{q} \nmid \mathfrak{d}, t(\mathfrak{q})=j\right\}\right|}{\left|\left\{\mathfrak{q} \in \mathcal{P}_{i}(X): \mathfrak{q} \nmid \mathfrak{d}\right\}\right|}=c_{i, j} .
$$

More precisely, if $\mathcal{L}$ is a function satisfying Theorem 8.1, then for every $Y>\mathbf{N o}$ and every $X>\mathcal{L}(Y)$ we have

$$
\left|\frac{\left|\left\{\mathfrak{q} \in \mathcal{P}_{i}(X): \mathfrak{q} \nmid \mathfrak{d}, t(\mathfrak{q})=j\right\}\right|}{\left|\left\{\mathfrak{q} \in \mathcal{P}_{i}(X): \mathfrak{q} \nmid \mathfrak{d}\right\}\right|}-c_{i, j}\right| \leqslant \frac{1}{Y} .
$$

If $p \mid[K(T): K]$ then the same is true for $i=1, j=0,1$.
Proof. Let $r:=\operatorname{rk}(\omega)$, let $F_{\mathfrak{d}, \omega}$ be the field of Definition 9.2, and for every $\mathfrak{q} \notin \Sigma(\mathfrak{d})$ denote by $\operatorname{Frob}_{\mathfrak{q}} \in \operatorname{Gal}\left(F_{\mathfrak{d}, \omega} / K\right)$ a Frobenius automorphism for some choice of prime above $\mathfrak{q}$. We need to

## A Markov model for Selmer ranks in families of twists

interpret the different values of $t(\mathfrak{q})$ as Frobenius conditions on $\mathfrak{q}$. By Lemma 5.9, $\mathfrak{q} \in \mathcal{P}_{1}$ if and only if $\left.\mathrm{Frob}_{\mathfrak{q}}\right|_{K(T)}$ has order $p$, and $\mathfrak{q} \in \mathcal{P}_{2}$ if and only if $\left.\operatorname{Frob}_{\mathfrak{q}}\right|_{K(T)}=1$.

Suppose that $\mathfrak{q} \notin \Sigma(\mathfrak{d})$. Then $H_{\mathrm{ur}}^{1}\left(K_{\mathfrak{q}}, T\right) \cong T /\left(\mathrm{Frob}_{\mathfrak{q}}-1\right) T$, with the isomorphism given by evaluating 1-cocycles on Frob $_{\mathfrak{q}}$ (see, for example, [Ser65, § XIII.1]). Thus $t(\mathfrak{q})$ is the $\mathbf{F}_{p}$-dimension of the subspace

$$
\left\{c\left(\operatorname{Frob}_{\mathfrak{q}}\right): c \text { a cocycle representing a class in } \operatorname{Sel}(T, \omega)\right\} \subset T /\left(\operatorname{Frob}_{\mathfrak{q}}-1\right) T .
$$

Let $\phi: \operatorname{Gal}\left(F_{\mathfrak{0}, \omega} / K(T)\right) \xrightarrow{\sim} \operatorname{Hom}(\operatorname{Sel}(T, \omega), T)$ be the isomorphism of Proposition 9.3(ii).
We first consider the case $\mathfrak{q} \in \mathcal{P}_{2}$, or equivalently $\operatorname{Frob}_{\mathfrak{q}} \in \operatorname{Gal}\left(F_{\mathfrak{d}, \omega} / K(T)\right)$. In this case $T /\left(\operatorname{Frob}_{\mathfrak{q}}-1\right) T=T$. For $0 \leqslant j \leqslant 2$ let

$$
R_{j}:=\left\{f \in \operatorname{Hom}(\operatorname{Sel}(T, \omega), T): \operatorname{dim}_{\mathbf{F}_{p}} \operatorname{image}(f)=j\right\}
$$

and let $S_{j}:=\phi^{-1}\left(R_{j}\right) \subset \operatorname{Gal}\left(F_{\mathfrak{\mathfrak { d }}, \omega} / K(T)\right) \subset \operatorname{Gal}\left(F_{\mathfrak{\mathfrak { l }}, \omega} / K\right)$. Then

$$
t(\mathfrak{q})=j \Longleftrightarrow \operatorname{dim}_{\mathbf{F}_{p}}\left\{c\left(\operatorname{Frob}_{\mathfrak{q}}\right): c \in \operatorname{Sel}(T, \omega)\right\}=j \Longleftrightarrow \operatorname{Frob}_{\mathfrak{q}} \in S_{j} .
$$

Set $S^{\prime}:=S_{j}$ and $S:=\operatorname{Gal}\left(F_{\mathfrak{J}, \omega} / K(T)\right)$. Since $\mathcal{L}$ satisfies Theorem 8.1, for every $X>\mathcal{L}(Y)$ we have (using Proposition 9.3(iii))

$$
\left|\frac{\left|\left\{\mathfrak{q} \in \mathcal{P}_{2}(X), \mathfrak{q} \nmid \mathfrak{d}: t(\mathfrak{q})=j\right\}\right|}{\left|\left\{\mathfrak{q} \in \mathcal{P}_{2}(X): \mathfrak{q} \nmid \mathfrak{d}\right\}\right|}-\frac{\left|R_{j}\right|}{\left[F_{\mathfrak{d}, \omega}: K(T)\right]}\right| \leqslant \frac{1}{Y} .
$$

By Proposition 9.3(i) we have $\left[F_{\mathfrak{0}, \omega}: K(T)\right]=p^{2 r}$. Clearly $\left|R_{0}\right|=1$. We can decompose $R_{1}$ into a disjoint union, over the $p+1$ lines $\ell \subset T$, of the nonzero elements of $\operatorname{Hom}(\operatorname{Sel}(T, \omega), \ell)$. Thus

$$
\begin{aligned}
& \left|R_{1}\right|=(p+1)\left(p^{r}-1\right), \\
& \left|R_{2}\right|=p^{2 r}-\left|R_{0}\right|-\left|R_{1}\right|=p^{2 r}-(p+1)\left(p^{r}-1\right)-1=p^{2 r}-(p+1) p^{r}+p .
\end{aligned}
$$

This proves the proposition when $i=2$.
Now suppose that $p \mid[K(T): K]$, so that $\mathcal{P}_{1}$ is nonempty. Suppose that $\mathfrak{q} \in \mathcal{P}_{1}$, or equivalently Frob $\left._{\mathfrak{q}}\right|_{K(T)}$ has order $p$, so $T /\left(\operatorname{Frob}_{\mathfrak{q}}-1\right) T$ has dimension 1. Let

$$
S^{\prime}:=\left\{g \in \operatorname{Gal}\left(F_{\mathfrak{0}, \omega} / K\right):\left.g\right|_{K(T)} \text { has order } p \text { and } c(g) \in(g-1) T \text { for every } c \in \operatorname{Sel}(T, \omega)\right\}
$$

(note that $c(g)$ is well defined in $T /(g-1) T$, independent of the choice of cocycle representing $c$ ). Then $S^{\prime}$ is closed under conjugation, and $t(\mathfrak{q})=0$ if and only if $\mathrm{Frob}_{\mathfrak{q}} \in S^{\prime}$. If we set

$$
S:=\left\{g \in \operatorname{Gal}\left(F_{\mathfrak{0}, \omega} / K\right):\left.g\right|_{K(T)} \text { has order } p\right\}
$$

then again, since $\mathcal{L}$ satisfies Theorem 8.1, for every $X>\mathcal{L}(Y)$ we have

$$
\left|\frac{\left|\left\{\mathfrak{q} \in \mathcal{P}_{1}(X): t(\mathfrak{q})=0\right\}\right|}{\left|\left\{\mathfrak{q} \in \mathcal{P}_{1}(X): \mathfrak{q} \nmid \mathfrak{d}\right\}\right|}-\frac{\left|S^{\prime}\right|}{|S|}\right| \leqslant \frac{1}{Y} .
$$

It remains to compute $\left|S^{\prime}\right| /|S|$. Let $U:=\{g \in \operatorname{Gal}(K(T) / K): g$ has order $p\}$. Then we have $|S|=|U|\left[F_{\mathfrak{d}, \omega}: K(T)\right]=p^{2 r}|U|$.

Suppose that $g \in \operatorname{Gal}\left(F_{\mathfrak{0}, \omega} / K\right)$ and $\left.g\right|_{K(T)} \in U$. Evaluation at $g$ induces a homomorphism $\lambda_{g}: \operatorname{Sel}(T, \omega) \rightarrow T /(g-1) T$, and we have $g \in S^{\prime}$ if and only if $\lambda_{g}$ is identically zero. If $h \in$ $\operatorname{Gal}\left(F_{\mathfrak{0}, \omega} / K(T)\right)$, then in $T /(g-1) T=T /(g h-1) T$ we have

$$
\lambda_{g h}(c)=c(g h)=c(g)+g c(h)=\lambda_{g}(c)+c(h) \quad \text { for every } c \in \operatorname{Sel}(T, \omega) .
$$

## Z. Klagsbrun, B. Mazur and K. Rubin

Thus $g h \in S^{\prime}$ if and only if the image of $h$ under the composition

$$
\operatorname{Gal}\left(F_{\mathfrak{\jmath}, \omega} / K(T)\right) \xrightarrow{\phi} \operatorname{Hom}(\operatorname{Sel}(T, \omega), T) \rightarrow \operatorname{Hom}(\operatorname{Sel}(T, \omega), T /(g-1) T)
$$

is equal to $-\lambda_{g}$. Since $\phi$ is an isomorphism, there are exactly $p^{r}$ such $h$. It follows that the restriction map $S^{\prime} \rightarrow U$ is surjective, and all fibers have order $p^{r}$. Therefore $\left|S^{\prime}\right|=p^{r}|U|$, which proves the proposition when $i=1, j=0$. The result for $i=j=1$ follows since

$$
\left\{\mathfrak{q} \in \mathcal{P}_{1}: \mathfrak{q} \nmid \mathfrak{d}\right\}=\left\{\mathfrak{q} \in \mathcal{P}_{1}: \mathfrak{q} \nmid \mathfrak{d}, t(\mathfrak{q})=0\right\} \coprod\left\{\mathfrak{q} \in \mathcal{P}_{1}: \mathfrak{q} \nmid \mathfrak{d}, t(\mathfrak{q})=1\right\} .
$$

Theorem 9.5. For every subset $S \subset \Omega_{1}$, the rank data $\Omega^{S}$ on $\mathcal{D}$ are governed (in the sense of Definition 3.10) by the mod $p$ Lagrangian Markov operator $M_{L}$ of Definition 2.1, and every function $\mathcal{L}$ satisfying Theorem 8.1 is a convergence rate for $\left(\Omega^{S}, M_{L}\right)$.

Proof. Fix $\mathfrak{d} \in \mathcal{D}$ and $\omega \in \Omega_{\mathfrak{d}}^{S}$, and let $r:=\operatorname{rk}(\omega)$. As in Definition 7.1, for $\mathfrak{q} \in \mathcal{P}_{1} \cup \mathcal{P}_{2}, \mathfrak{q} \nmid \mathfrak{d}$, let $t(\mathfrak{q}):=\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{loc}_{\mathfrak{q}}(\operatorname{Sel}(T, \omega))$. If $X>0$ and $\mathcal{P}_{i}(X)$ is nonempty, define

$$
\begin{aligned}
F_{i}(X, s) & :=\frac{\sum_{\mathfrak{q} \in \mathcal{P}_{i}(X), \mathfrak{q} \nmid \mathfrak{d}}\left|\left\{\chi \in \eta_{\mathfrak{o}, \mathfrak{q}}^{-1}(\omega): \operatorname{rk}(\chi)=s\right\}\right|}{\sum_{\mathfrak{q} \in \mathcal{P}_{i}(X), \mathfrak{q} \nmid \mathfrak{d}}\left|\eta_{\mathfrak{l}, \mathfrak{q}}^{-1}(\omega)\right|}, \\
\Phi_{i, j}(\mathfrak{d}, X) & :=\frac{\left|\left\{\mathfrak{q} \in \mathcal{P}_{i}(X): \mathfrak{q} \nmid \mathfrak{d}, t(\mathfrak{q})=j\right\}\right|}{\left|\left\{\mathfrak{q} \in \mathcal{P}_{i}(X): \mathfrak{q} \nmid \mathfrak{d}\right\}\right|} .
\end{aligned}
$$

If $\mathcal{P}_{1}$ is nonempty, i.e. $p \mid[K(T): K]$, then Proposition $7.2($ i,ii) shows that

$$
F_{1}(X, s)= \begin{cases}0 & \text { if } s \neq r \pm 1 \\ \Phi_{1,1}(\mathfrak{d}, X) & s=r-1 \\ \Phi_{1,0}(\mathfrak{d}, X) & s=r+1\end{cases}
$$

Similarly, Proposition 7.2(i,iii) shows that

$$
F_{2}(X, s)= \begin{cases}0 & \text { if } s \neq r \text { or } r \pm 2 \\ \Phi_{2,2}(\mathfrak{d}, X) & s=r-2 \\ \Phi_{2,1}(\mathfrak{d}, X)+\frac{p-1}{p} \Phi_{2,0}(\mathfrak{d}, X) & s=r \\ \frac{1}{p} \Phi_{2,0}(\mathfrak{d}, X) & s=r+2\end{cases}
$$

Proposition 9.4 computes $\lim _{X \rightarrow \infty} \Phi_{i, j}(\mathfrak{d}, X)$ for $j \leqslant i$, giving

$$
\begin{aligned}
& \lim _{X \rightarrow \infty} F_{1}(X, s)= \begin{cases}0 & \text { if } s \neq r \pm 1, \\
1-p^{-r} & s=r-1, \\
p^{-r} & s=r+1 ;\end{cases} \\
& \lim _{X \rightarrow \infty} F_{2}(X, s)= \begin{cases}0 & \text { if } s \neq r \text { or } r \pm 2, \\
1-(p+1) p^{-r}+p^{1-2 r} & s=r-2, \\
p^{1-r}+p^{-r}-p^{1-2 r}-p^{-1-2 r} & s=r, \\
p^{-1-2 r} & s=r+2 .\end{cases}
\end{aligned}
$$

The right-hand values above are equal to the matrix entries in $M_{L}$ and $M_{L}^{2}$, so this shows that $M_{L}$ governs the rank data for $\Omega^{S}$ for every $S$. Using the more precise convergence in Proposition 9.4 shows that $\mathcal{L}$ is a convergence rate for $\left(\Omega^{S}, M_{L}\right)$.

## A Markov model for Selmer ranks in families of twists

## 10. Passage from global characters to semi-local characters

We continue to assume that (9.1)-(9.3) all hold.
Theorems 4.3 and 9.5 give us the machinery we need to see how Selmer ranks are distributed over the twists by collections of local characters. However, we want to compute the distribution of Selmer ranks over twists by global characters. In this section we use class field theory to study the map from global characters to collections of local characters. More precisely, we make the following definitions.

Definition 10.1. Recall that $\mathcal{C}(K)=\operatorname{Hom}\left(G_{K}, \boldsymbol{\mu}_{p}\right)$. If $\chi \in \mathcal{C}(K)$ and $v$ is a place of $K$, we let $\chi_{v} \in \mathcal{C}\left(K_{v}\right)$ denote the restriction of $\chi$ to $G_{K_{v}}$. For $\mathfrak{d} \in \mathcal{D}$, define

$$
\mathcal{C}(\mathfrak{d}):=\left\{\chi \in \mathcal{C}(K): \chi \text { is ramified at all } \mathfrak{q} \text { dividing } \mathfrak{d} \text {, and unramified outside of } \Sigma(\mathfrak{d}) \cup \mathcal{P}_{0}\right\} .
$$

In other words, $\mathcal{C}(\mathfrak{d})$ is the fiber over $\mathfrak{d}$ of the map $\mathcal{C}(K) \rightarrow \mathcal{D}$ that sends $\chi$ to the part of its conductor supported on $\mathcal{P}_{1} \cup \mathcal{P}_{2}$, so we have $\mathcal{C}(K)=\coprod_{\mathfrak{d} \in \mathcal{D}} \mathcal{C}(\mathfrak{d})$. For $X>0$, define:
$-\mathcal{C}(X)=\{\chi \in \mathcal{C}(K): \chi$ is unramified outside of $\Sigma \cup\{\mathfrak{q}: \mathbf{N} \mathfrak{q}<X\}\} ;$
$-\mathcal{C}(\mathfrak{d}, X):=\mathcal{C}(\mathfrak{d}) \cap \mathcal{C}(X)$.
Let $\eta_{\mathfrak{0}}: \mathcal{C}(\mathfrak{d}) \rightarrow \Omega_{\mathfrak{d}}$ be the natural map $\chi \rightarrow\left(\ldots, \chi_{v}, \ldots\right)_{v \in \Sigma(\mathfrak{d})}$, where $\chi_{v} \in \mathcal{C}\left(K_{v}\right)$ is the restriction of $\chi$ to $G_{K_{v}}$.

The main result of this section is Theorem 10.7, which describes the image and fibers of the map $\eta_{\mathfrak{0}}: \mathcal{C}(\mathfrak{d}, X) \rightarrow \Omega_{\mathfrak{d}}$. For large $X$ this map is surjective if $p>2$ (its image depends on the parity of $w(\mathfrak{d})$ if $p=2$ ), and all nonempty fibers have the same cardinality. Theorem 10.7 will enable us to pass from averages over $\Omega_{\mathfrak{d}}$ to averages over $\mathcal{C}(\mathfrak{d}, X)$.

Lemma 10.2. Let $G:=\operatorname{Gal}\left(K(T) / K\left(\boldsymbol{\mu}_{p}\right)\right)$.
(i) There is a $\sigma \in G$ such that $\sigma^{p} \neq 1$.
(ii) If $p>3$ then $G$ has no quotient of order $p$.
(iii) If $p=3$ and $3\left||G|\right.$, then $G=\mathrm{SL}_{2}(T)$.

Proof. Fix an $\mathbf{F}_{p}$-basis of $T$, so that we can identify $\operatorname{Gal}\left(K(T) / K\left(\boldsymbol{\mu}_{p}\right)\right)$ with a subgroup of $\mathrm{SL}_{2}\left(\mathbf{F}_{p}\right)$.

Case 1: $p \nmid|G|$. Our assumption (9.1) implies that $G \neq 1$. In this case (i) is satisfied by any nontrivial $\sigma \in G$, (ii) is trivial, and (iii) is vacuous.

Case 2: $G=\mathrm{SL}_{2}\left(\mathbf{F}_{p}\right)$. All three assertions follow directly in this case.
Case 3: $p\left||G|\right.$ and $G \neq \mathrm{SL}_{2}\left(\mathbf{F}_{p}\right)$. In this case, [Ser72, Proposition 15] shows that $G$ is contained in a Borel subgroup of $\mathrm{SL}_{2}\left(\mathbf{F}_{p}\right)$. It follows from (9.2) that $G$ commutes only with scalar matrices in $M_{2 \times 2}\left(\mathbf{F}_{p}\right)$, and so there is a subgroup $H \subset \mathbf{F}_{p}^{\times}, H \not \subset\{ \pm 1\}$, such that, with a suitable choice of basis,

$$
G=\left\{\left(\begin{array}{cc}
a & b \\
0 & a^{-1}
\end{array}\right): a \in H, b \in \mathbf{F}_{p}\right\} .
$$

Now (i) and (ii) follow directly, and we must have $p>|H| \geqslant 3$ in this case.
Lemma 10.3. Define the subgroup $\mathcal{A} \subset K^{\times} /\left(K^{\times}\right)^{p}$ by

$$
\mathcal{A}:=\operatorname{ker}\left(K^{\times} /\left(K^{\times}\right)^{p} \rightarrow K(T)^{\times} /\left(K(T)^{\times}\right)^{p}\right) .
$$

## Z. Klagsbrun, B. Mazur and K. Rubin

(i) $\mathcal{A}$ is cyclic, generated by an element $\Delta \in \mathcal{O}_{K, \Sigma}^{\times}$.
(ii) If $p=2$, then $|\mathcal{A}|=2$.
(iii) If $p=3$, then $|\mathcal{A}|=1$ or 3 , and $\mathcal{A}=1$ if $3 \nmid[K(T): K]$.
(iv) If $p>3$, then $\mathcal{A}=1$.

Proof. Assertion (i) is [KMR13, Lemma 6.2], which also showed that

$$
\begin{equation*}
\mathcal{A}=\operatorname{Hom}\left(\operatorname{Gal}\left(K(T) / K\left(\boldsymbol{\mu}_{p}\right)\right), \boldsymbol{\mu}_{p}\right)^{\operatorname{Gal}\left(K\left(\boldsymbol{\mu}_{p}\right) / K\right)} . \tag{10.1}
\end{equation*}
$$

Assumption (9.2) implies that if $p=2$, then $\operatorname{Gal}(K(T) / K) \cong S_{3}$. Now (ii) and (iii) follow directly from (10.1).

If $p>3$, then (iv) follows from (10.1) and Lemma 10.2 (ii).
Fix once and for all a $\Delta \in \mathcal{O}_{K, \Sigma}^{\times}$as in Lemma 10.3. Recall from Definition 5.11 that we have $\Omega_{1}:=\prod_{v \in \Sigma} \mathcal{C}\left(K_{v}\right)$, and more generally $\Omega_{\mathfrak{d}}^{S}:=S \times \prod_{\mathfrak{q} \mid \mathfrak{d}} \mathcal{C}_{\mathrm{ram}}\left(K_{\mathfrak{q}}\right)$ for $\mathfrak{d} \in \mathcal{D}$ and $S \subset \Omega_{1}$. For each $v$, local class field theory identifies $\mathcal{C}\left(K_{v}\right)$ with $\operatorname{Hom}\left(K_{v}^{\times}, \boldsymbol{\mu}_{p}\right)$.
Lemma 10.4. Suppose that $G$ and $H$ are abelian groups, and $J \subset G \times H$ is a subgroup. Let $\pi_{G}$ and $\pi_{H}$ be the projection maps from $G \times H$ to $G$ and $H$, respectively. Let $J_{0}:=\operatorname{ker}\left(J \xrightarrow{\pi_{G}} G / G^{p}\right)$.
(i) The image of the natural map $\operatorname{Hom}\left((G \times H) / J, \boldsymbol{\mu}_{p}\right) \rightarrow \operatorname{Hom}\left(H, \boldsymbol{\mu}_{p}\right)$ is $\operatorname{Hom}\left(H / \pi_{H}\left(J_{0}\right), \boldsymbol{\mu}_{p}\right)$.
(ii) If $J / J^{p} \rightarrow G / G^{p}$ is injective, then $\operatorname{Hom}\left((G \times H) / J, \boldsymbol{\mu}_{p}\right) \rightarrow \operatorname{Hom}\left(H, \boldsymbol{\mu}_{p}\right)$ is surjective.

Proof. We have an exact sequence of $\mathbf{F}_{p}$-vector spaces

$$
0 \longrightarrow \pi_{H}\left(J_{0}\right) H^{p} / H^{p} \longrightarrow H / H^{p} \longrightarrow(G \times H) / J(G \times H)^{p} .
$$

Assertion (i) follows by applying $\operatorname{Hom}\left(\cdot, \boldsymbol{\mu}_{p}\right)$, and (ii) follows directly from (i).
Lemma 10.5. Suppose that $\mathcal{L}$ is a function satisfying Theorem $8.1, \mathfrak{d} \in \mathcal{D}, \alpha \in \mathcal{O}_{K, \Sigma(\mathfrak{d})}^{\times} /\left(\mathcal{O}_{K, \Sigma(\mathfrak{d})}^{\times}\right)^{p}$, and $\alpha \neq 1$. If $p>2$, or if $p=2$ and $\alpha \neq \Delta$, then there is a $\mathfrak{q} \in \mathcal{P}_{0}$ with $\mathbf{N q} \leqslant \mathcal{L}(\mathbf{N} \mathfrak{d})$ such that $\alpha \notin\left(\mathcal{O}_{\mathfrak{q}}^{\times}\right)^{p}$.

Proof. Suppose first that $\alpha \notin \mathcal{A}$. Then by definition $\alpha \notin\left(K(T)^{\times}\right)^{p}$, so

$$
K\left(\boldsymbol{\mu}_{p}, \alpha^{1 / p}\right) \cap K(T)=K\left(\boldsymbol{\mu}_{p}\right) .
$$

By Lemma 10.2(i), there is a $\sigma \in \operatorname{Gal}\left(K(T) / K\left(\boldsymbol{\mu}_{p}\right)\right)$ such that $\sigma^{p} \neq 1$. Choose an element $\tau \in \operatorname{Gal}\left(K\left(T, \alpha^{1 / p}\right) / K\left(\boldsymbol{\mu}_{p}\right)\right)$ such that $\left.\tau\right|_{K(T)}=\sigma$ and $\left.\tau\right|_{K\left(\boldsymbol{\mu}_{p}, \alpha^{1 / p}\right)} \neq 1$. By Theorem 8.1 applied with $F=K\left(T, \alpha^{1 / p}\right)$ and $S$ equal to the conjugacy class of $\tau$, we see that there is a prime $\mathfrak{q} \notin \Sigma(\mathfrak{d})$ with $\mathbf{N q} \leqslant \mathcal{L}(\mathbf{N} \mathfrak{d})$ whose Frobenius in $\operatorname{Gal}\left(K\left(T, \alpha^{1 / p}\right) / K\right)$ is in the conjugacy class of $\tau$. For such a prime $\mathfrak{q}$, we have that $\mathfrak{q} \in \mathcal{P}_{0}$ by Lemma 5.9(iii) and $\alpha \notin\left(\mathcal{O}_{\mathfrak{q} \times}\right)^{p}$.

By Lemma 10.3, it remains only to consider the case $p=3,3 \mid[K(T): K]$, and $1 \neq \alpha \in \mathcal{A}$. Then $K\left(\boldsymbol{\mu}_{3}, \alpha^{1 / 3}\right) \subset K(T)$, and $\operatorname{Gal}\left(K(T) / K\left(\boldsymbol{\mu}_{3}\right)\right) \cong \mathrm{SL}_{2}\left(\mathbf{F}_{3}\right)$ by Lemma $10.2(\mathrm{iii})$, so we can choose an element $\sigma \in \operatorname{Gal}\left(K(T) / K\left(\boldsymbol{\mu}_{3}\right)\right)$ of order 6 . Applying Theorem 8.1 with $F=K(T)$ and $S$ equal to the conjugacy class of $\sigma$, we see that there is a prime $\mathfrak{q} \notin \Sigma$ with $\mathbf{N q} \leqslant \mathcal{L}(\mathbf{N} \mathfrak{d})$ whose Frobenius in $\operatorname{Gal}(K(T) / K)$ is in the conjugacy class of $\sigma$. For such a prime $\mathfrak{q}$, we have that $\mathfrak{q} \in \mathcal{P}_{0}$ by Lemma 5.9(iii), and $\sigma$ acts nontrivially on $\alpha^{1 / 3} \in K(T)$, so $\alpha \notin\left(\mathcal{O}_{\mathfrak{q}}^{\times}\right)^{3}$. This completes the proof.

## A Markov model for Selmer ranks in families of twists

$$
S^{+}:=\left\{\omega \in \Omega_{1}: \operatorname{sign}_{\Delta}(\omega)=1\right\}, \quad S^{-}:=\left\{\omega \in \Omega_{1}: \operatorname{sign}_{\Delta}(\omega)=-1\right\}
$$

We will abbreviate $\Omega_{\mathfrak{d}}^{+}=\Omega_{\mathfrak{d}}^{S^{+}}$and $\Omega_{\mathfrak{d}}^{-}=\Omega_{\mathfrak{d}}^{S^{-}}$.
Recall that $\eta_{\mathfrak{D}}: \mathcal{C}(\mathfrak{d}) \rightarrow \Omega_{\mathfrak{d}}$ is the natural restriction map.
Proposition 10.7. Suppose that $\mathfrak{d} \in \mathcal{D}, \mathcal{L}$ is a function satisfying Theorem 8.1, and $X>\mathcal{L}(\mathbf{N} \mathfrak{d})$.
(i) If $p>2$ then $\eta_{\mathfrak{0}}: \mathcal{C}(\mathfrak{d}, X) \rightarrow \Omega_{\mathfrak{d}}$ is surjective.
(ii) If $p=2$ then $\eta_{\mathfrak{d}}(\mathcal{C}(\mathfrak{d}, X))= \begin{cases}\Omega_{\mathfrak{d}}^{+} & \text {if } w(\mathfrak{d}) \text { is even, } \\ \Omega_{\mathfrak{d}}^{-} & \text {if } w(\mathfrak{d}) \text { is odd. }\end{cases}$
(iii) For every $\omega \in \eta_{\mathfrak{0}}(\mathcal{C}(\mathfrak{d}, X))$ we have

$$
\frac{\left|\left\{\chi \in \mathcal{C}(\mathfrak{d}, X): \eta_{\mathfrak{d}}(\chi)=\omega\right\}\right|}{|\mathcal{C}(\mathfrak{d}, X)|}= \begin{cases}1 /\left|\Omega_{\mathfrak{d}}\right| & \text { if } p>2 \\ 2 /\left|\Omega_{\mathfrak{d}}\right| & \text { if } p=2\end{cases}
$$

Proof. By our assumption (7.1), we have $\operatorname{Pic}\left(\mathcal{O}_{K, \Sigma(\mathfrak{d})}\right)=0$. Thus global class field theory gives

$$
\mathcal{C}(K)=\operatorname{Hom}\left(\mathbf{A}_{K}^{\times} / K^{\times}, \boldsymbol{\mu}_{p}\right)=\operatorname{Hom}\left(\left(\prod_{v \in \Sigma(\mathfrak{d})} K_{v}^{\times} \times \prod_{\mathfrak{q} \notin \Sigma(\mathfrak{d})} \mathcal{O}_{\mathfrak{q}}^{\times}\right) / \mathcal{O}_{K, \Sigma(\mathfrak{d})}^{\times}, \boldsymbol{\mu}_{p}\right)
$$

Let

$$
\begin{aligned}
& Q_{1}:=\left\{\mathfrak{q}: \mathfrak{q} \in \mathcal{P}_{0}, \mathbf{N} \mathfrak{q} \leqslant X\right\}, \\
& Q_{2}:=\left\{\mathfrak{q}: \mathfrak{q} \in \mathcal{P}_{1} \cup \mathcal{P}_{2}, \mathfrak{q} \nmid \mathfrak{d}\right\} \cup\left\{\mathfrak{q}: \mathfrak{q} \in \mathcal{P}_{0}, \mathbf{N} \mathfrak{q}>X\right\} .
\end{aligned}
$$

We apply Lemma 10.4 with

$$
G:=\prod_{\mathfrak{q} \in Q_{1}} \mathcal{O}_{\mathfrak{q}}^{\times}, \quad H:=\prod_{v \in \Sigma(\mathfrak{p})} K_{v}^{\times} \times \prod_{\mathfrak{q} \in Q_{2}} \mathcal{O}_{\mathfrak{q}}^{\times}, \quad J:=\mathcal{O}_{K, \Sigma(\mathfrak{p})}^{\times}
$$

Note that for $\chi \in \mathcal{C}(K)$, we have

$$
\chi \in \mathcal{C}(\mathfrak{d}, X) \Longleftrightarrow \chi_{\mathfrak{q}}\left(\mathcal{O}_{\mathfrak{q}}^{\times}\right)=1 \text { for } \mathfrak{q} \in Q_{2} \text { and } \chi_{\mathfrak{q}}\left(\mathcal{O}_{\mathfrak{q}}^{\times}\right) \neq 1 \text { if } \mathfrak{q} \mid \mathfrak{d}
$$

If $p>2$, then combining (7.2), Lemma 10.5, and Lemma 10.4(ii), we see that the restriction map

$$
\begin{equation*}
\mathcal{C}(K) \longrightarrow \operatorname{Hom}\left(\prod_{v \in \Sigma(\mathfrak{d})} K_{v}^{\times} \times \prod_{\mathfrak{q} \in Q_{2}} \mathcal{O}_{\mathfrak{q}}^{\times}, \boldsymbol{\mu}_{p}\right) \tag{10.2}
\end{equation*}
$$

is surjective. Thus for every $\omega \in \Omega_{\mathfrak{d}}$ we can find a $\chi \in \mathcal{C}(K)$, unramified outside of $\Sigma, \mathfrak{d}$, and $Q_{1}$, that restricts to $\omega$. Such a $\chi$ necessarily belongs to $\mathcal{C}(\mathfrak{d}, X)$, and this shows that $\eta_{\mathfrak{0}}: \mathcal{C}(\mathfrak{d}, X) \rightarrow \Omega_{\mathfrak{d}}$ is surjective, proving (i).

Similarly, if $p=2$ then $\Delta \neq 1$ by Lemma 10.3(ii). Lemma 10.5 shows that $\Delta$ generates $\operatorname{ker}\left(J / J^{2} \rightarrow G / G^{2}\right)$, so by Lemma $10.4(\mathrm{i})$ we see that the image of (10.2) is exactly $\operatorname{Hom}\left(\left(\prod_{v \in \Sigma(\mathfrak{d})} K_{v}^{\times} \times \prod_{\mathfrak{q} \in Q_{2}} \mathcal{O}_{\mathfrak{q}}^{\times}\right) /\langle\Delta\rangle,\{ \pm 1\}\right)$. By [KMR13, Lemma 6.5], $\Delta \in\left(\mathcal{O}_{\mathfrak{q}}^{\times}\right)^{2}$ if $\mathfrak{q} \in \mathcal{P}_{2}$, and $\Delta$ generates $\mathcal{O}_{\mathfrak{q}}^{\times} /\left(\mathcal{O}_{\mathfrak{q}}^{\times}\right)^{2}$ if $\mathfrak{q} \in \mathcal{P}_{1}$. It followsthat for $\omega \in \Omega_{\mathfrak{d}}$, we have $\omega \in \eta_{\mathfrak{d}}(\mathcal{C}(\mathfrak{d}, X))$ if and only if $\operatorname{sign}_{\Delta}(\omega)=(-1)^{w(\mathfrak{~})}$. This proves (ii).

If $\chi_{1}, \chi_{2} \in \mathcal{C}(\mathfrak{d}, X)$, then $\eta_{\mathfrak{d}}\left(\chi_{1}\right)=\eta_{\mathfrak{d}}\left(\chi_{2}\right)$ if and only if $\chi_{1} \chi_{2}^{-1} \in \mathcal{C}(1, X) \cap \operatorname{ker}\left(\eta_{1}\right)$. Since $\mathcal{C}(\mathfrak{d}, X)$ is stable under multiplication by the group $\mathcal{C}(1, X)$, it follows that all nonempty fibers of $\eta_{0}: \mathcal{C}(\mathfrak{d}, X) \rightarrow \Omega_{\mathfrak{0}}$ have the same order $\left|\mathcal{C}(1, X) \cap \operatorname{ker}\left(\eta_{1}\right)\right|$. This proves (iii).

## Z. Klagsbrun, B. Mazur and K. Rubin

## 11. Rank densities

In this section we use Theorems 4.3 and 9.5 , and the results of $\S 10$, to prove Theorem A of the introduction (Corollary 11.12 below). We will deduce this from a finer result (Theorem 11.6).

Fix for this section a function $\mathcal{L}$ satisfying Theorem 8.1. By Theorem 9.5, $\mathcal{L}$ is a convergence rate function for $\left(\Omega, M_{L}\right)$. We continue to assume that (9.1)-(9.3) hold. Recall that if $\omega \in \Omega_{\mathfrak{0}}$ then $\operatorname{rk}(\omega):=\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}(T, \omega)$. If $\chi \in \mathcal{C}(K)$ then $\chi \in \mathcal{C}(\mathfrak{d})$ for a (unique) $\mathfrak{d} \in \mathcal{D}$, and we define

$$
\operatorname{Sel}(T, \chi)=\operatorname{Sel}\left(T, \eta_{\mathrm{D}}(\chi)\right)
$$

where $\eta_{\mathfrak{0}}: \mathcal{C}(\mathfrak{d}) \rightarrow \Omega_{\mathfrak{d}}$ is the product of restriction maps (Definition 10.1). If $A$ is an elliptic curve over $K$ and $T=A[2]$ with the natural twisting data as in $\S 6$, then Proposition 6.4 shows that $\operatorname{Sel}(T, \chi)=\operatorname{Sel}_{2}\left(A^{\chi}\right)$, the classical 2-Selmer group of the quadratic twist $A^{\chi}$ of $A$.

Define $\operatorname{rk}(\chi):=\operatorname{dim}_{\mathbf{F}_{p}} \operatorname{Sel}(T, \chi)$.
Definition 11.1. Suppose that $\mathfrak{d} \in \mathcal{D}$. If $p=2$, let $\Omega_{\mathfrak{d}}^{+}$and $\Omega_{\mathfrak{d}}^{-}$be the sets given by Definition 10.6. To simplify the notation, define $\Omega_{\mathfrak{d}}^{+}:=\Omega_{\mathfrak{d}}^{-}:=\Omega_{\mathfrak{d}}$ if $p>2$. Let $E_{\mathfrak{d}}^{ \pm} \in W$ be the probability distribution corresponding to $\Omega_{\mathfrak{d}}^{ \pm}$as in Definition 3.7.

Proposition 11.2. If $X>\mathcal{L}(\mathbf{N d})$, then

$$
\frac{|\{\chi \in \mathcal{C}(\mathfrak{d}, X): \operatorname{rk}(\chi)=n\}|}{|\mathcal{C}(\mathfrak{d}, X)|}= \begin{cases}E_{\mathfrak{d}}^{+}(n) & \text { if } w(\mathfrak{d}) \text { is even, } \\ E_{\mathfrak{d}}^{-}(n) & \text { if } w(\mathfrak{d}) \text { is odd. }\end{cases}
$$

Proof. Let $\nu:=(-1)^{w(\mathfrak{d})}$, and fix $X>\mathcal{L}(\mathbf{N} \mathfrak{d})$. Proposition 10.7 shows that the natural map $\eta_{\mathfrak{0}}: \mathcal{C}(\mathfrak{d}, X) \rightarrow \Omega_{\mathfrak{0}}^{\nu}$ is surjective, and all fibers have the same order. By definition, if $\chi \in \mathcal{C}(\mathfrak{d})$ then $\operatorname{Sel}(T, \chi)=\operatorname{Sel}\left(T, \eta_{\mathfrak{0}}(\chi)\right)$. Therefore

$$
\frac{|\{\chi \in \mathcal{C}(\mathfrak{d}, X): \operatorname{rk}(\chi)=n\}|}{|\mathcal{C}(\mathfrak{d}, X)|}=\frac{\left|\left\{\omega \in \Omega_{\mathfrak{d}}^{\nu}: \operatorname{rk}(\omega)=n\right\}\right|}{\left|\Omega_{\mathfrak{d}}^{\nu}\right|}=E_{\mathfrak{d}}^{\nu}(n) .
$$

Lemma 11.3. Suppose that $\mathfrak{d} \in \mathcal{D}$. If $m$ is the number of primes dividing $\mathfrak{d}$, then for every $X>\mathcal{L}(\mathbf{N} \mathfrak{d})$ we have $|\mathcal{C}(\mathfrak{d}, X)|=(p-1)^{m}|\mathcal{C}(1, X)|$.

Proof. Suppose that $\mathfrak{d}=\mathfrak{q}_{1} \cdots \mathfrak{q}_{m}$. For each $j$, by Proposition 10.7 we can fix a character $\chi_{j} \in$ $\mathcal{C}\left(\mathfrak{q}_{j}, X\right)$ that is (necessarily ramified at $\mathfrak{q}_{j}$ and) unramified outside of $\mathfrak{q}_{j}, \Sigma$ and $\mathcal{P}_{0}$. Then every $\chi \in \mathcal{C}(\mathfrak{d}, X)$ can be written uniquely as a product of powers of the $\chi_{j}$ times a character in $\mathcal{C}(1, X)$, so the map

$$
\left(\mathbf{F}_{p}^{\times}\right)^{m} \times \mathcal{C}(1, X) \longrightarrow \mathcal{C}(\mathfrak{d}, X)
$$

defined by $\left(n_{1}, \ldots, n_{m}, \psi\right) \mapsto \chi_{1}^{n_{1}} \cdots \chi_{m}^{n_{m}} \psi$ is a bijection.
Use the chosen convergence rate function $\mathcal{L}$ to define $\mathcal{D}_{m, k, X} \subset \mathcal{D}$ as in Definition 3.14, for $m, k \in \mathbf{Z}_{\geqslant 0}$ and $X \in \mathbf{R}_{>0}$.

Definition 11.4. For $m, k \geqslant 0$, define

$$
\mathcal{B}_{m, k, X}:=\coprod_{\mathfrak{d} \in \mathcal{D}_{m, k}, X} \mathcal{C}\left(\mathfrak{d}, \mathcal{L}\left(L_{m+1}(X)\right)\right) \subset \mathcal{C}(K)
$$

with $L_{m+1}(X)$ as in Definition 3.14. We call the collection of sets of characters $\mathcal{B}_{m, k, X}$ a fan structure on $\mathcal{C}(K)$.

## A Markov model for Selmer ranks in families of twists

Remark 11.5. The sets $\mathcal{B}_{m, k, X}$ depend on $T$ and $\Sigma$, because they depend on the sets $\mathcal{P}_{0}, \mathcal{P}_{1}$, and $\mathcal{P}_{2}$. But they do not depend on the chosen twisting data. Thus if we take two elliptic curves $A, A^{\prime}$ with $A[p] \cong A^{\prime}[p]$ as $G_{K}$-modules, and take the same $\Sigma$ and $\mathcal{L}$ for both $A$ and $A^{\prime}$, then the sets $\mathcal{B}_{m, k, X}$ are the same for $A$ and $A^{\prime}$.
Theorem 11.6. Suppose that (9.1)-(9.3) hold. If $m, k, n \geqslant 0$ and $\bigcup_{X} \mathcal{D}_{m, k, X}$ is nonempty, then

$$
\lim _{X \rightarrow \infty} \frac{\left|\left\{\chi \in \mathcal{B}_{m, k, X}: \operatorname{rk}(\chi)=n\right\}\right|}{\left|\mathcal{B}_{m, k, X}\right|}= \begin{cases}M^{k}\left(E_{1}^{+}\right)(n) & \text { if } k \text { is even, } \\ M^{k}\left(E_{1}^{-}\right)(n) & \text { if } k \text { is odd. }\end{cases}
$$

Proof. Let $b_{m}(X):=\mathcal{L}\left(L_{m+1}(X)\right)$. By definition of $\mathcal{B}_{m, k, X}$,

$$
\frac{\left|\left\{\chi \in \mathcal{B}_{m, k, X}: \operatorname{rk}(\chi)=n\right\}\right|}{\left|\mathcal{B}_{m, k, X}\right|}=\frac{\sum_{\mathfrak{d} \in \mathcal{D}_{m, k, X}}\left|\left\{\chi \in \mathcal{C}\left(\mathfrak{d}, b_{m}(X)\right): \operatorname{rk}(\chi)=n\right\}\right|}{\sum_{\mathfrak{d} \in \mathcal{D}_{m, k, X}}\left|\mathcal{C}\left(\mathfrak{d}, b_{m}(X)\right)\right|}
$$

By Lemma 11.3, $\left|\mathcal{C}\left(\mathfrak{d}, b_{m}(X)\right)\right|$ is independent of $\mathfrak{d} \in \mathcal{D}_{m, k}$, so

$$
\begin{aligned}
\frac{\left|\left\{\chi \in \mathcal{B}_{m, k, X}: \operatorname{rk}(\chi)=n\right\}\right|}{\left|\mathcal{B}_{m, k, X}\right|} & =\frac{1}{\left|\mathcal{D}_{m, k, X}\right|} \sum_{\mathfrak{d} \in \mathcal{D}_{m, k, X}} \frac{\left|\left\{\chi \in \mathcal{C}\left(\mathfrak{d}, b_{m}(X)\right): \operatorname{rk}(\chi)=n\right\}\right|}{\left|\mathcal{C}\left(\mathfrak{d}, b_{m}(X)\right)\right|} \\
& =\frac{1}{\left|\mathcal{D}_{m, k, X}\right|} \sum_{\mathfrak{d} \in \mathcal{D}_{m, k, X}} E_{\mathfrak{d}}^{(-1)^{k}}(n)
\end{aligned}
$$

using Proposition 11.2 for the final equality. By Theorem 4.3 (using Corollary 7.3 to see that the hypotheses of Theorem 4.3 hold), as $X$ grows thisconverges to $M^{k}\left(E_{1}^{(-1)^{k}}\right)(n)$.

## Lemma 11.7.

(i) If $p \nmid[K(T): K]$, then $\bigcup_{X} \mathcal{D}_{m, k, X}$ is nonempty if and only $k=2 m$.
(ii) If $p \mid[K(T): K]$, then $\bigcup_{X} \mathcal{D}_{m, k, X}$ is nonempty if and only $m \leqslant k \leqslant 2 m$.

Proof. Recall that $\mathcal{D}_{m, k, X}$ consists of $\mathfrak{d}$ that are products of $m$ primes, with $w(\mathfrak{d})=k$.
By Lemma 5.9, if $p \nmid[K(T): K]$ then $\mathcal{P}_{1}$ is empty, so $w(\mathfrak{d})$ is twice the number of primes dividing $\mathfrak{d}$.

If $p \mid[K(T): K]$, then $\mathcal{P}_{1}$ and $\mathcal{P}_{2}$ are both nonempty. So if $\mathfrak{d}$ is a product of $m$ primes, then $m \leqslant w(\mathfrak{d}) \leqslant 2 m$. Conversely, if $m \leqslant k \leqslant 2 m$ then every $\mathfrak{d}$ that is a product of $2 m-k$ primes from $\mathcal{P}_{1}$ and $k-m$ primes from $\mathcal{P}_{2}$ will have $m$ prime factors and $w(\mathfrak{d})=k$.

Recall the probability distributions $\mathbf{E}^{+}, \mathbf{E}^{-}$given explicitly by Definition 2.2.
Corollary 11.8. Suppose that (9.1)-(9.3) hold. We have

$$
\begin{array}{r}
\lim _{m, k \rightarrow \infty} \lim _{X \rightarrow \infty} \frac{\left|\left\{\chi \in \mathcal{B}_{m, 2 k}(X): \operatorname{rk}(\chi)=n\right\}\right|}{\left|\mathcal{B}_{m, 2 k}(X)\right|}=\left(1-\rho\left(E_{1}^{+}\right)\right) \mathbf{E}^{+}(n)+\rho\left(E_{1}^{+}\right) \mathbf{E}^{-}(n), \\
\lim _{m, k \rightarrow \infty} \lim _{X \rightarrow \infty} \frac{\left|\left\{\chi \in \mathcal{B}_{m, 2 k+1}(X): \operatorname{rk}(\chi)=n\right\}\right|}{\left|\mathcal{B}_{m, 2 k+1}(X)\right|}=\rho\left(E_{1}^{-}\right) \mathbf{E}^{+}(n)+\left(1-\rho\left(E_{1}^{-}\right)\right) \mathbf{E}^{-}(n),
\end{array}
$$

where the limits are over any sequence of pairs ( $m, k$ ) tending to infinity such that $\bigcup_{X} \mathcal{D}_{m, 2 k, X}$ is nonempty (for the first equality) and $\bigcup_{X} \mathcal{D}_{m, 2 k+1, X}$ is nonempty (for the second equality).

Proof. The corollary follows directly from Theorem 11.6 and Proposition 2.4.

## Z. Klagsbrun, B. Mazur and K. Rubin

Suppose for the rest of this section that $p=2, A$ is an elliptic curve over $K$, and $T=A[2]$ with the natural twisting data of $\S 6$. Let $\Delta \in \mathcal{O}_{K, \Sigma}$ be the discriminant of some model of $A$; by [KMR13, Lemma 6.3], this $\Delta$ satisfies Lemma 10.3(i).
Definition 11.9. If $v \in \Sigma$ and $\psi, \psi^{\prime} \in \mathcal{C}\left(K_{v}\right)$, let

$$
h\left(\psi, \psi^{\prime}\right):=\operatorname{dim}_{\mathbf{F}_{p}}\left(\alpha_{v}(\psi) /\left(\alpha_{v}(\psi) \cap \alpha_{v}\left(\psi^{\prime}\right)\right)\right)
$$

where $\alpha_{v}: \mathcal{C}\left(K_{v}\right) \rightarrow \mathcal{H}\left(q_{v}\right)$ is given by the twisting data, and define

$$
\begin{gathered}
\gamma_{v}(\psi):=(-1)^{h\left(\mathbf{1}_{v}, \psi\right)} \psi(\Delta) \in\{ \pm 1\}, \\
\delta_{v}=\frac{1}{\left|\mathcal{C}\left(K_{v}\right)\right|} \sum_{\psi \in \mathcal{C}\left(K_{v}\right)} \gamma_{v}(\psi), \quad \text { and } \quad \delta(A / K):=\frac{(-1)^{\mathrm{rk}(\mathbf{1})}}{2} \prod_{v \in \Sigma} \delta_{v} .
\end{gathered}
$$

The quantity $\delta(A / K)$ is the 'disparity' mentioned in the introduction (see [KMR13, Theorem 7.6]).

Lemma 11.10. Suppose that $\operatorname{Gal}(K(A[2]) / K) \cong S_{3}$, and that $\Sigma$ contains a prime $\mathfrak{q} \nmid 2$ where $A$ has good reduction and $\Delta \notin\left(K_{\mathfrak{q}}^{\times}\right)^{2}$. Then

$$
\rho\left(E_{1}^{+}\right)=\frac{1}{2}-\delta(A / K) \quad \text { and } \quad \rho\left(E_{1}^{-}\right)=\frac{1}{2}+\delta(A / K) .
$$

Proof. We will show that $\rho\left(E_{1}^{+}\right)+\rho\left(E_{1}^{-}\right)=1$ and $\rho\left(E_{1}^{-}\right)-\rho\left(E_{1}^{+}\right)=2 \delta(A / K)$.
Since $\left|\Omega_{1}^{+}\right|=\left|\Omega_{1}^{-}\right|=\left|\Omega_{1}\right| / 2$, we have

$$
\begin{aligned}
\rho\left(E_{1}^{+}\right)+\rho\left(E_{1}^{-}\right) & =\frac{\mid\left\{\omega \in \Omega_{1}^{+}: \operatorname{rk}(\omega) \text { is odd }\right\} \mid}{\left|\Omega_{1}^{+}\right|}+\frac{\mid\left\{\omega \in \Omega_{1}^{-}: \operatorname{rk}(\omega) \text { is odd }\right\} \mid}{\left|\Omega_{1}^{-}\right|} \\
& =2 \frac{\mid\left\{\omega \in \Omega_{1}: \operatorname{rk}(\omega) \text { is odd }\right\} \mid}{\left|\Omega_{1}\right|} .
\end{aligned}
$$

Let $\mathfrak{q}$ be as in the statement of the lemma, and fix $\varphi \in \Omega_{1}$ such that $\varphi_{\mathfrak{q}}(\Delta)=-1$, and $\varphi_{v}=\mathbf{1}_{v}$ if $v \neq \mathfrak{q}$. Then multiplication by $\varphi$ permutes the elements of $\Omega_{1}$.

If $\omega \in \Omega_{1}$ then by Theorem 5.13 (for the first congruence) and [KMR13, Lemma 5.6] applied to the Lagrangian subspaces $\alpha_{v}\left(\mathbf{1}_{\mathfrak{q}}\right), \alpha_{v}\left(\omega_{\mathfrak{q}}\right)$, and $\alpha_{v}\left(\omega_{\mathfrak{q}} \varphi_{\mathfrak{q}}\right)$ (for the second congruence) we have

$$
\begin{equation*}
\operatorname{rk}(\omega \varphi)-\operatorname{rk}(\omega) \equiv h\left(\omega_{\mathfrak{q}}, \omega_{\mathfrak{q}} \varphi_{\mathfrak{q}}\right) \equiv h\left(\mathbf{1}_{\mathfrak{q}}, \omega_{\mathfrak{q}}\right)+h\left(\mathbf{1}_{\mathfrak{q}}, \omega_{\mathfrak{q}} \varphi_{\mathfrak{q}}\right) \quad(\bmod 2) . \tag{11.1}
\end{equation*}
$$

By [Kra81, Proposition 3] we have

$$
(-1)^{h\left(\mathbf{1}_{\mathfrak{q}}, \omega_{\mathfrak{q}}\right)}=\omega_{\mathfrak{q}}(\Delta), \quad(-1)^{h\left(\mathbf{1}_{\mathfrak{q}}, \omega_{\mathfrak{q}} \varphi_{\mathfrak{q}}\right)}=\omega_{\mathfrak{q}} \varphi_{\mathfrak{q}}(\Delta)=-\omega_{\mathfrak{q}}(\Delta),
$$

so the right-hand side of (11.1) is odd. Therefore $\operatorname{rk}(\omega)$ is odd for exactly half of the $\omega \in \Omega_{1}$, and we conclude that $\rho\left(E_{1}^{+}\right)+\rho\left(E_{1}^{-}\right)=1$.

By Theorem 5.13, if $\omega \in \Omega_{1}$ we have

$$
(-1)^{\mathrm{rk}(\mathbf{1})+\mathrm{rk}(\omega)}=\prod_{v \in \Sigma}(-1)^{h\left(\mathbf{1}_{v}, \omega_{v}\right)}=\operatorname{sign}_{\Delta}(\omega) \prod_{v \in \Sigma} \gamma_{v}\left(\omega_{v}\right) .
$$

Therefore

$$
\operatorname{rk}(\omega) \text { is odd } \Longleftrightarrow\left\{\begin{array}{l}
\omega \in \Omega_{1}^{+} \text {and } \prod_{v \in \Sigma} \gamma_{v}\left(\omega_{v}\right) \neq(-1)^{\mathrm{rk}(\mathbf{1})}, \text { or } \\
\omega \in \Omega_{1}^{-} \text {and } \prod_{v \in \Sigma} \gamma_{v}\left(\omega_{v}\right)=(-1)^{\mathrm{rk}(\mathbf{1})}
\end{array}\right.
$$

## A Markov model for Selmer ranks in families of twists

Thus

$$
\begin{aligned}
\rho\left(E_{1}^{-}\right)-\rho\left(E_{1}^{+}\right) & =\frac{\mid\left\{\omega \in \Omega_{1}^{-}: \operatorname{rk}(\omega) \text { is odd }\right\} \mid}{\left|\Omega_{1}^{-}\right|}-\frac{\mid\left\{\omega \in \Omega_{1}^{+}: \operatorname{rk}(\omega) \text { is odd }\right\} \mid}{\left|\Omega_{1}^{+}\right|} \\
& =\sum_{\omega \in \Omega_{1}^{-}} \frac{1+(-1)^{\mathrm{rk}(\mathbf{1})} \prod_{v \in \Sigma} \gamma_{v}\left(\omega_{v}\right)}{\left|\Omega_{1}\right|}-\sum_{\omega \in \Omega_{1}^{+}} \frac{1-(-1)^{\mathrm{rk}(\mathbf{1})} \prod_{v \in \Sigma} \gamma_{v}\left(\omega_{v}\right)}{\left|\Omega_{1}\right|} \\
& =(-1)^{\operatorname{rk}(\mathbf{1})} \frac{\sum_{\omega \in \Omega_{1}} \prod_{v \in \Sigma} \gamma_{v}\left(\omega_{v}\right)}{\left|\Omega_{1}\right|}=2 \delta(A / K) .
\end{aligned}
$$

This proves the lemma.
Remark 11.11. The assumption in Lemma 11.10 and Corollary 11.12 below that $\Sigma$ contains a prime $\mathfrak{q} \nmid 2$ where $A$ has good reduction and $\Delta \notin\left(K_{\mathfrak{q}}^{\times}\right)^{2}$ can always be satisfied by adding to $\Sigma$ any prime in $\mathcal{P}_{1}$.

Corollary 11.12. Suppose that $\operatorname{Gal}(K(A[2]) / K) \cong S_{3}$, and that $\Sigma$ contains a prime $\mathfrak{q} \nmid 2$ where $A$ has good reduction and $\Delta \notin\left(K_{\mathfrak{q}}^{\times}\right)^{2}$. Let $\mathcal{B}_{m}(X):=\bigcup_{k} \mathcal{B}_{m, k, X}$ with $\mathcal{B}_{m, k, X}$ as in Definition 11.4. Then for every $n \geqslant 0$ we have

$$
\lim _{m \rightarrow \infty} \lim _{X \rightarrow \infty} \frac{\left|\left\{\chi \in \mathcal{B}_{m}(X): \operatorname{rk}(\chi)=n\right\}\right|}{\left|\mathcal{B}_{m}(X)\right|}=\left(\frac{1}{2}+\delta(A / K)\right) \mathbf{E}^{+}(n)+\left(\frac{1}{2}-\delta(A / K)\right) \mathbf{E}^{-}(n) .
$$

Proof. This follows directly from Corollary 11.8 and Lemma 11.10, since

$$
1-\rho\left(E_{1}^{+}\right)=\rho\left(E_{1}^{-}\right)=\frac{1}{2}+\delta(A / K) .
$$
