# Some Results of an $\mathrm{H} \alpha$ Survey in the Taurus Dark Clouds 

Alisher S. Hojaev<br>Ulugbek Astronomical Institute, Uzbek Academy of Sciences, Astronomicheskaya St 33, Tashkent 700052, Uzbekistan<br>hojaev@saturn.silk.org

#### Abstract

From a series of $4^{\circ}$ objective-prism plates obtained on the 1 m Schmidt telescope of the Byurakan Astrophysical Observatory, 20 new $\mathrm{H} \alpha$ emission line stars were found. The intensity of $\mathrm{H} \alpha$ emission line was evaluated for these stars. An additional sample of probable $\mathrm{H} \alpha$ emission stars was also found. We present here details and some observational features of these stars. The total number of $\mathrm{H} \alpha$ emission line stars estimated for the surveyed area is about 80 .

Keywords: objective prism survey - $\mathrm{H} \alpha$ objects - pre-main-sequence stars

## 1 Introduction

$\mathrm{H} \alpha$ emission in stellar spectra is one of the distinct indicators of chromospheric activity of dwarf stars, especially in the early stages of their evolution. These stars usually form so-called T-associations and are often T Tauri type stars when studied in detail. Stars with strong $\mathrm{H} \alpha$ emission can be found in large-scale spectral surveys of star forming regions (hereafter SFR) carried out using wide field cameras equipped with an objective prism. We have used this method to search for and study $\mathrm{H} \alpha$ emission line stars in the nearest SFR in the Taurus dark clouds (hereafter TDC). Preliminary results were presented by Parsamian \& Hojaev (1985).

## 2 Observations

The observations were carried out on the 1 m ( 40 inch) Schmidt telescope of the Byurakan Astrophysical Observatory with a $4^{\circ}$ objective prism. We used a Schott RG1 filter with Kodak 103a-E, IIa-E and 103-F type plates. The observational details are presented in Table 1.

The total survey region patrol time was about 10 hours. Since the observations covered a few superposed fields along the extent of the dark clouds (see Figure 1), the overall survey area was approximately 50 sq. deg. with the common centre at R.A. $(1950 \cdot 0)=04^{h} 30^{m}$ and Decl. (1950•0) $=+24^{\circ}$ (the region of the Taurus 1-Taurus 3 T-associations). Different exposure times were selected to clearly reveal $\mathrm{H} \alpha$ emission in stars of different brightness. The survey's limiting magnitude was $M_{p g}>19 \cdot 5$. The evaluation of the relative $\mathrm{H} \alpha$ emission intensity was made using the conventional five-grade scale proposed by Haro (1953).

## 3 New H $\alpha$ Emission Stars

Examination of the plates revealed 20 new stars with significant $\mathrm{H} \alpha$ line emission. The emission
intensities were evaluated for all these stars. The data on these new stars are given in Table 2. In consecutive columns we present the Byurakan star number $\mathrm{BH}-\mathrm{a}$, the 1950 coordinates, photographic magnitude and $\mathrm{H} \alpha$ line intensity $I[\mathrm{H}-\mathrm{a}]$.

## 4 Probable H $\alpha$ Emission Stars

A further 18 suspected $\mathrm{H} \alpha$ emission stars were found. These stars had very weak $\mathrm{H} \alpha$ lines or their $\mathrm{H} \alpha$ line emission was detected on one plate only. Details of these stars are given in Table 3.

## 5 Discussion

The spatial distribution of the new $\mathrm{H} \alpha$ stars in the TDC region is shown in Figure 1. The solid lines represent the contours of the dark clouds with visual absorption $\mathrm{A}(\mathrm{V}) \geq 2 \cdot 0$. The dashed lines outline the fields surveyed. As seen in Figure 1 the new $\mathrm{H} \alpha$ emission stars are concentrated in the clouds themselves and have the same type of location as known $\mathrm{H} \alpha$ emission stars and pre-main-sequence (PMS) stars in general. Consideration of known and newly discovered stars shows a grouping effect to the local centres. Many previously discovered stars with H $\alpha$ emission (Joy 1949; Haro et al. 1953) have turned out to be PMS stars with stochastic or irregular variability (Cohen \& Kuhi 1979; Kholopov et al. 1987; Herbig \& Bell 1988, and so on). Some of the $\mathrm{H} \alpha$ line stars discovered during our research, for example BV 5 (Hojaev 1986), B 41 and SB 33 (Hojaev 1984), B 4 (Hojaev 1983), are also such stars. It is clear that the spectral variability of these young stars has a connection with their photometric variability and is irregular in nature. The latter allows us to apply the method for an estimation of the total number of irregular variable stars in the clusters suggested by Ambartsumian (1977) and Parsamian (1981) in order to calculate the total number of $\mathrm{H} \alpha$ emission stars in the TDC region. We have used 36 stars having evaluations of $\mathrm{H} \alpha$ line

intensities for four periods: 1952 (Haro et al. 1953), 1958-62 (Dolidze 1975), 1970 and 1983-84 (this work). We evaluated the expected total number of TDCs stars with $\mathrm{H} \alpha$ line emission according to the formulae given in Parsamian \& Hojaev (1985) as $N=77$. The total number of stars with $\mathrm{H} \alpha$ emission which can be revealed from our plates should be about 80 for the surveyed TDC area (i.e. about 1.6 per sq. deg.).

In summary, 20 new stars with $\mathrm{H} \alpha$ line emission were found in the TDC region. The fact that the $\mathrm{H} \alpha$ line emission of these stars was not discovered earlier can be explained as either variability of the line intensity or the weakness of the line in the stars studied. We can assume that these stars do not differ from the Orion population stars by the nature of the $\mathrm{H} \alpha$ emission variability.

Figure 1-Spatial distribution of the new $\mathrm{H} \alpha$ stars in the TDC region.

The existence of large number of young stars and related objects as well as the other indicators of youth (e.g. infrared sources, molecular clouds, cometary nebulae, Herbig-Haro objects, flare stars, T Tauri stars and other PMS stars) allows us to presume that the associations of SFR in the TDC, including this sample, have the same age as the associations in the Orion and Monocerotis SFRs.

## Acknowledgments

I am grateful to Quentin Parker for his discussions and support of this work.
