Abstract

Introduction
Childhood obesity is associated with multiple cardio-metabolic abnormalities. A sensitive hypothesis underlying these alterations is oxidative stress, shown to be present in obesity, often accompanied by a diminished antioxidant defense. Specifically, plasma vitamin concentrations have been observed to be associated with obesity in adults and children. However, their association with cardio-metabolic alterations in children is less clear.

Materials and Methods
985 children (49.2% males, 71.7% prepubertal, 71.9% excess weight) were recruited in a case-control study of obesity in three Spanish hospitals. Pubertal status was assessed and anthropometry (weight, height), systolic and diastolic blood pressure (SBP, DBP) and serum glucose, insulin, triacylglycerols (TAG) and high-density lipoprotein cholesterol (HDL-C) were measured. Plasma concentrations of tocopherols and carotenes were determined with HPLC-MS and referred to TAG. Children were classified as MU if showing one or more of these criteria: SBP or DBP ≥ 90th percentile (age, sex, height), serum TAG > 90th percentile (age, sex), HDL-C < 10th percentile (age, sex), glucose ≥ 100 mg/dL or elevated HOMA-IR (≥ 2.5 prepubertal, ≥ 3.38 pubertal males, ≥ 3.905 pubertal females). Non-fulfillment was indicative of MH status. General linear models adjusted for sex, age, recruitment center and BMI were used to evaluate differences in vitamins between MU and MH children.

Results
Prepubertal and pubertal children with excess weight showed lower tocopherols (Pre: 0.133 ± 0.061 vs 0.165 ± 0.065, P < 0.001; Pub: 0.120 ± 0.057 vs 0.163 ± 0.066, P < 0.001) and carotenes (Pre: 15.63 ± 13.72 vs 30.31 ± 26.04, P < 0.001; Pub: 12.34 ± 9.86 vs 22.98 ± 19.25, P < 0.001) plasma concentrations than normal-weight children. MU prepubertal and pubertal children showed lower tocopherols (Pre: 0.120 ± 0.056 vs 0.165 ± 0.064, P < 0.001; Pub: 0.111 ± 0.051 vs 0.154 ± 0.066, P < 0.001) and carotenes (Pre: 14.07 ± 12.61 vs 25.97 ± 21.94, P < 0.001; Pub: 10.90 ± 8.54 vs 19.03 ± 14.58, P < 0.001) plasma concentrations than MH children, independently of BMI. Individual MU components analyses showed similar associations between tocopherols and carotenes and insulin resistance, low HDL-C values and hypertriglyceridemia in prepubertal children; and between tocopherols and carotenes and elevated SBP, hyperglycemia and hypertriglyceridemia in pubertal children.

Discussion
Our findings agree with previous studies that showed decreased plasma concentrations of tocopherols and carotenes in children with obesity. However, we observe further implications of low circulating concentrations of non-enzymatic antioxidants in terms of their negative association with cardio-metabolic alterations such as insulin resistance and dyslipidemia in prepubertal and pubertal children, independently of BMI. These results must be considered when designing prevention and treatment strategies of obesity and its complications.
