time. The effects of the above cannot be ruled out.

Undoubtedly, with their excellent study design
the authors have proved that cognitive impairment
occurs in chronically ill bipolar affective disorder
patients, but whether this reflects an integral part of
the disease process remains to be determined.

Neuropsychological function in manic-depressive psychosis.

Visual fields in Gilles de la Tourette Syndrome

Sir: Gilles de la Tourette (GTS) is a complex
disorder characterised by multiple motor and one
or more vocal tics (DSM–III–R; APA, 1987). It has
been shown that GTS is a genetic disorder and the
inheritance pattern is consistent with autosomal
dominant transmission with incomplete but high
penetration (Eapen, 1993). In such a disorder there
is always a quest for biological markers. Enoch et al
(1988) described anomalous kinetic visual fields in
100% of children with GTS. It was suggested that
visual field defects may serve as a genetic marker for
GTS. Repka & Singer (1992) performed automated
static perimetry on 18 children with GTS. They
demonstrated field defects in 25% of cases, however,
they observed that these rates approximated to
those observed in patients undergoing first time
visual field testing.

We undertook a prospective controlled study to
which 12 GTS patients (24 eyes), and 12 (24 eyes)
aged, sex-matched controls were recruited. No ocular
disease was detected in any of the subjects, none had
previously undergone visual field testing. Visual field
tests were performed using a Humphrey Field
Analyser running a central 24-2 full threshold test.
Data collected included mean deviation (MD)
scores, an indication of the overall field abnormality
and corrected pattern standard deviation (CPSD)
scores, localised field defects. Twenty-one out of
24 visual field tests in each group were reliable ac-
cording to the reliability indices built into the field
analyser software and were included in statistical
analysis. There were no statistically significant dif-
ferences in either MD (P=0.08) or CPSD (P=0.21)
between GTS and control eyes (see Table 1 for
results for Humphrey fields). The difference in MD
approached significance, and a larger sample might
be expected to yield a significant result. However, the
MD score for a particular patient would not serve as
a biological marker for GTS since there is a large
overlap of MD scores in the GTS and control
groups. Our study indicates a trend for a higher
negative MD score in GTS patients, but we conclude
that visual fields do not serve as a useful biological
marker.

CORRESPONDENCE

A HUNDRED YEARS AGO

The alleged increase of insanity

It is eminently satisfactory that the Lunacy Commissioners are beginning to recognise the importance of age incidence in the consideration of the statistics of insanity with a view to the determination of the problem whether the constant increase in the number of the insane under treatment in England and Wales really signifies an increasing prevalence of lunacy, or rather of occurring cases of insanity. In their recent annual reports it is true that the Commissioners have constantly expressed their opinion that the large increase in the number of known lunatics is mainly due to causes other than an increase in the prevalence of insanity as an active disease. They have, however, until now turned a deaf ear to the urgent appeal for statistics of the ages of the patients annually admitted to the lunatic asylums, and of the ages of the patients who die year by year in those asylums. We are glad to note in the recently issued report a first instalment of such age statistics, which, if continued for a series of years, and if amplified, will in a few years afford the means of throwing much light upon this important and interesting problem. It is pointed out that in recent years there has been a marked increase in the number and proportion of admitted cases of mental decay resulting solely from old age. In proof of this the Commissioners show that in 1883 the admissions to asylums of persons aged upwards of sixty years were equal to 12.5% of the total admissions; in 1888 this proportion had increased to 13.2%; and in 1893 it had further increased to 14.7%. These statistics are based upon information contained in the annual reports issued by county and borough asylums, and conclusively prove that the cases admitted above the age of sixty years have increased at a far more rapid rate than the admissions under that age. These cases represent, probably, to a large extent transfers from workhouses to asylums, but from whatever cause the increase arises it can scarcely be seriously asserted that this increase of cases of senile mental decay represents an increase of true insanity. These figures, moreover, throw some light upon the age incidence of the persons returned in England and Wales as mentally deranged at the three Censuses in 1871, 1881, and 1891. The ratio per 1000 of the English population returned as mentally deranged under the age of forty-five years was 2.24 in 1871, 2.29 in 1881, and 2.26 in 1891. Thus the ratio of insanity to population at these ages remained practically stationary during this period of twenty years. Above the age of forty-five years, however, the calculation of the ratio of insanity gives very different results; the ratio was 6.35 per 1000 in 1871, 7.40 in 1881, and 8.02 in 1891. In the absence of information as to the ages of cases admitted to asylums it was impossible to ascertain how much of this increased incidence of mental derangement upon elderly persons was due to what may correctly be called the accumulation of cases caused by improved treatment of the insane in asylums, and how much to an increase in the number of admissions of cases of senile dementia. The figures given in the Lunacy Commissioners' last report established beyond doubt the steady increase, both actual and relative, in the admission of cases of so-called insanity above the age of sixty years. The important bearing of these figures in the direction of disproving the reality of the alleged increase of insanity in this country will, it may be hoped, induce the Commissioners to give more complete statistics of the ages of the annual admissions to all asylums for the insane in future reports.
