(Received 7 November 2007 – Revised 8 July 2008 – Accepted 14 July 2008 – First published online 19 September 2008)

The aim of the present study was to investigate whether ethanol extracts of Psoralea corylifolia L. (PCE) and its active component protect against bone loss in ovariectomised rats. We screened oestrogenic activities of the main extract fractions using in vitro assays and identified bakuchiol as the most active oestrogenic component by HPLC and LC/MS, and then demonstrated that bakuchiol had strong binding affinity for oestrogen receptor (ER) α. Seventy female Sprague–Dawley rats were assigned to either a sham-operated group (n 10) or an ovariectomised group (n 60). The ovariectomised group was subdivided into six groups, each containing ten rats: vehicle group, two bakuchiol-treated groups (dose of 15 mg/kg per d or 30 mg/kg per d; ten rats for each group), two PCE-supplemented groups (0·25 % or 0·5 % extracts of diets; ten rats for each group) and a 17β-oestradiol (E2)-treated group (20 μg/kg per d). We recorded weight and feed intake every week, and killed all animals after 6 weeks. Blood was collected, and the uterus, kidneys and livers were removed. Bakuchiol has a three-fold higher binding affinity for ERα than for ERβ. Bakuchiol and PCE treatments had no uterotrophic activity even though they demonstrated oestrogenic activity in the in vitro assays. Bakuchiol and PCE treatments reduced postmenopausal bone loss by increasing alkaline phosphatase, Ca concentrations, serum E2 concentration and bone mineral density, and by decreasing the inorganic P level. The present study indicated that bakuchiol and PCE treatments could protect against bone loss.

Psoralea corylifolia: Bakuchiol: Ovariectomy: Bone loss

Menopausal women have a higher risk of uterine fibroids, fibrocystic breast disease, breast or uterine cancer, CHD and obesity(1,2). The most prevalent disease in postmenopausal women is osteoporosis, a disorder of excess skeletal fragility caused partly by changes in bone microstructure(3,4). Hormone-replacement therapy (HRT) is currently used to treat osteoporosis or to reduce the symptoms of the menopause, even though HRT has a risk of adverse side effects including breast cancer and endometrial adenocarcinoma(5).

Concerns about the adverse side effects of HRT have led to interest in phyto-oestrogens, which are natural alternatives to HRT. Treatment with phyto-oestrogens such as equol, genistein and daidzein has shown favourable effects on bone metabolism, lipid metabolism, obesity and inhibition of menopausal symptoms(6–8). However, they are also associated with uterotrophic effects, which may increase the risk of endometrial cancer(7,9). Therefore, the development of new phyto-oestrogens with minimal uterotrophic effects is an urgent research focus.

Psoralea corylifolia L. is a widely used medicinal plant in Asia and India(5,10). The seeds of P. corylifolia L. exert antioxiative, antimicrobial and anti-inflammatory activities(11–13). Recent research suggests that P. corylifolia has potent oestrogenic effects and that its seeds may be a useful remedy for bone fractures, osteomalacia and osteoporosis(10,14). Components derived from P. corylifolia, including bakuchiol, corylifolia, corilin, psoralidin and isobavachin, have strong antioxidant activities(11), and corilin and bavachin have been shown to stimulate osteoblastic proliferation(15). However, little information is available concerning the oestrogenic characteristics of P. corylifolia L. in animal models.

In the present study, we screened the most oestrogenic component derived from P. corylifolia L. by two different in vitro assays, and identified the active component by instrumental analyses such as HPLC and LC/MS, and then compared binding affinities of the component for oestrogen receptor (ER) α and ERβ. We also evaluated the effects of P. corylifolia extracts and its active component on body-weight gain, uterine weight and bone loss in ovariectomised rats.

Experimental methods

Materials and sample preparation

Psoralea corylifolia L. seeds were purchased from a commercial supplier of herbs and pharmaceuticals (Seongnam, Republic of Korea) and were identified by Professor Y. M. Park, supplier of herbs and pharmaceuticals (Seongnam, Republic of Korea) and were identified by Professor Y. M. Park, supplier of herbs and pharmaceuticals (Seongnam, Republic of Korea) and were identified by Professor Y. M. Park.
Department of Life Science, Cheongju University (Cheonju, Republic of Korea). Voucher specimens (KFRI-PM03220) were preserved in the Korea Food Research Institute. Psoralen and bavachinin were purchased from Sigma Co. (St Louis, MO, USA), and bakuchiol, bavachalcone, isobavachalcone, bavachromene and isobavachromene isolated from P. corylifolia L. were obtained from the Korea Research Institute of Chemical Technology (Daejeon, Republic of Korea) as standard compounds for instrumental analyses (purities > 98% by HPLC, LC/MS, IR and 1H and 13C NMR spectroscopy). Catechin and 17β-oestradiol (E2) were purchased from Sigma Co. All other chemicals were of analytical grade (Fisher, Springfield, NJ, USA).

Dried seeds (300 g) were washed and boiled in 3 litres of 80% ethanol at 95℃ for 4 h, and the ethanol extract of P. corylifolia L. (PCE) was filtered through no. 2 filter paper (Whatman International Ltd, Maidstone, Kent, UK). A portion of PCE (1 ml) was used for fractionation, and the remainder was dried using a rotary evaporator (Rotavapor R-200; Buchi, Postfach, Switzerland) and stored at 4℃ until it was used to prepare the diets.

**Screening of oestrogenicity and identification of active component**

A quantity of 1 ml of PCE (25 5Bx) was diluted to 15 5Bx using 80% ethanol, and ninety fractions (each 5 ml) were obtained by gel chromatography (1.5 × 120 cm, 1 ml/min; Lipophilic Sephadex LH-20; Sigma Co.) eluting with 80% ethanol. The total polyphenol content was analysed using the Folin–Ciocalteu protocol(18). We used the in vitro yeast transactivation assay(17) and E-screen assay(18) for the screening of oestrogenicity. For the yeast transactivation assay, Saccharomyces cerevisiae ER+LYS 8127 was obtained from Dr K. S. Kang (Seoul National University, Republic of Korea) and stored in 20% glycerol at −80℃.

Experimental animals were fasted for 24 h before dissection. At necropsy, the uterus, livers, kidneys, blood and femurs were collected. Blood was centrifuged for 10 min at 3000 rpm to separate the serum. The uterus was weighed after the fat was trimmed and again after the connective tissue was trimmed, drained of intra-uterine fluid, and dried at 50℃ overnight. The livers and kidneys were also trimmed, weighed, and immediately stored at −70℃. Femurs were trimmed and stored at −70℃.

**Analysis of alkaline phosphatase, inorganic-phosphorus, calcium and 17β-oestradiol concentrations in serum**

Alkaline phosphatase (ALP), inorganic-phosphorus (IP) and Ca concentrations were measured using commercial reagent kits (Bayer Inc., West Haven, CT, USA) and read in an ADVIA 1650 Auto-analyser (Bayer Inc., Tokyo, Japan). Serum E2 concentration was measured using an E2 Enzyme Immunoassay test kit (NC-1111; Biocheck Inc., Foster City, CA, USA) and read at 450 nm in a UV spectrophotometer (V-530; Jasco, Tokyo, Japan). The E2 concentration of the specimens and controls run concurrently with the standards were calculated from the standard curve.

**Analysis of femoral bone mineral density**

The bone mineral density (BMD) of the trimmed femurs was analysed using peripheral dual-energy X-ray absorptiometry (models pDEXA Forearm X-Ray Bone Densitometer and pDEXA Sabre; Cooper Surgical Co., Fort Atkinson, WI, USA). BMD values were calculated using the same cross-section of proximal femurs.

**Statistical analysis**

All data are presented as mean values with their standard errors. Statistical analysis was performed using ANOVA followed by Duncan’s multiple-range test (P = 0.05) using a SAS program (SAS Institute Inc., Cary, NC, USA). The IC50 values of the compound binding affinity to ERα and

**Animal study: animals and diets**

Seventy female Sprague–Dawley rats, aged 5 weeks, were purchased from Orient Bio Inc. (Seongnam, Republic of Korea). The animals were housed under controlled temperature (20 ± 1℃), relative humidity (50–80%) and illumination (12 h light–dark) conditions and acclimatised for 1 week. The animals were either ovariectomised (six groups, ten rats in each group) or sham-operated (sham; one group of ten rats). After a 1-week recovery period, the animals were fed the following experimental diet based on AIN-93M (Dyets Inc., Bethlehem, PA, USA) for 6 weeks: two ovariectomised (OVX) groups were supplied with a PCE-containing diet (PCE at a low dose of 0.25% (PL) or at a high dose of 0.5% (PH)); three OVX groups were fed the control diet and injected subcutaneously with bakuchiol (bakuchiol at a low dose of 15 mg/kg per d (BL) or at a high dose of 30 mg/kg per d (BH)) or E2 (20 μg E2/kg per d; OE group), respectively. The sham and OVX groups were fed the control diet and were treated with the vehicle. Body weight and feed intake of all experimental animals were measured every week. The feed efficiency ratio was calculated as the weight gain (g) divided by feed intake (g).

**Serum and tissue collection**

Experimental animals were fasted for 24 h before dissection.
ERβ were calculated with SigmaPlot 9.0 software (Systat Software Inc., Richmond, CA, USA).

**Results**

**Identification of oestrogenic component from ethanol extract of Psoralea corylifolia L**

PCE was fractionated using Sephadex LH-20, and the total phenolic content of each fraction was measured (Appendix 1) and the oestrogenic activities of the main fractions were measured by an in vitro yeast transactivation assay and an E-screen assay. In the yeast transactivation assay, only the no. 40 fraction (1 μg/ml) resulted in 58 % β-galactosidase activity compared with 10^{-9} M-E2, whose concentration was shown as having the highest oestrogenicity. The other fractions did not exhibit any oestrogenic activity (Appendix 2 (A)). In the E-screen assay, the no. 40 fraction also showed oestrogenic activity in the range of 0·1–1 μg/ml. MCF-7 cells treated with the no. 40 fraction (0·1 μg/ml) showed proliferation at approximately two times higher than that induced by the control (Appendix 2 (B)). The no. 44 and no. 50 fractions showed no significant difference at 0·1 μg/ml compared with the control, while the cell growth increased by 120 and 150 % at 1·0 μg/ml, respectively. Taken together, these results indicate that the no. 40 fraction induced the highest effect on MCF-7 proliferation.

To identify the active component from the no. 40 fraction, we performed HPLC and LC/MS analyses. We separated only one peak by HPLC (Appendix 3 (A)), and its major fragmentation ion was m/z 257·3 in LC/MS (Appendix 3 (B)), which matched the analysis pattern of standard bakuchiol (m/z 256·4). Subsequently we identified the active component of no. 40 as bakuchiol.

To determine ER selectivity, the binding affinities of bakuchiol for ERα and ERβ were measured by an in vitro ER binding assay. The IC_{50} value for ERα was 1·34 × 10^{-6} M, while the IC_{50} value for ERβ was 1·20 × 10^{-6} M. These values were converted to RBA compared with positive controls (E2). The affinity of bakuchiol for ERα was three times higher than for ERβ (RBA_{ERα} = 1·51 and RBA_{ERβ} = 0·44), indicating that bakuchiol has higher selectivity for ERα.

**Effects of ethanol extract of Psoralea corylifolia L. and bakuchiol treatments in ovariectomised rats**

**Body and uterus weights.** After 6 weeks, the final body weight of the O VX group was 21·6 % higher than that of the sham group (P<0·01). The body weight was lower in the OE (78·4 %), PL (81·4 %) and PH (74·0 %) groups than in the O VX group. The amount of weight gained by the PL and PH groups differed significantly from the O VX group; however, the weight gain by the BL and BH groups did not differ from the O VX group (Table 1). The feed efficiency ratios were about 20 % lower in the OE, PL and PH groups than in the O VX group (P<0·001) despite no significant differences in feed intake. This indicates that PCE supplementation prevented body-weight gain in ovariectomised rats. The weight gain of the uterus was measured to evaluate the uterotrophic activity of bakuchiol and PCE treatments for 6 weeks. The absolute and relative wet uterine weights (weight per 100 g body weight) decreased by 87 % and 90 %, respectively, after the ovariectomy operation (Table 2). The uterine weight was 4·7 times higher in the O VX group than in the O VX group, although this difference was not significant for either bakuchiol or PCE treatment (P>0·05). Relative liver and absolute kidney weights showed slight changes after PCE treatments (Table 2).

**Alkaline phosphatase, calcium, inorganic-phosphorus and 17β-oestradiol concentrations in serum.** ALP, Ca and IP are key factors for bone calcification. ALP and IP concentrations increased by 13 and 23 % in the O VX group compared with the sham group. However, the ALP and IP values in PCE-treated animals were 17 and 10 % lower in the O VX group (P<0·001) and were 24 and 5 % lower in bakuchiol-treated animals in the O VX group (P<0·01; Table 3). Ca concentration was 3 % lower in the O VX group than in the sham group. PCE and bakuchiol treatment increased Ca levels above 2 % compared with the O VX group (P<0·01). These data suggest that both PCE supplements and bakuchiol administration suppressed ALP increases in bone turnover of post-ovariectomised rats.

The E2 concentration in serum was reduced by the ovariectomy. The E2 concentration was 16·9 pg/ml in...
Discussion

Based on the results of observational and epidemiological studies, phyto-oestrogens have been shown to help alleviate symptoms of menopause and to reduce the risk of CVD and oestrogen-dependent cancers. Despite evidence supporting the health benefits of phyto-oestrogens, genistein and soya protein stimulate tumour growth in a dose-dependent manner in ovariectomised athymic mice implanted with MCF-7 cells. Many new potent phyto-oestrogens from medicinal plants such as red clover, dong quai, soya and fo-ti have been investigated for development into new drugs that will hopefully provide alternatives to HRT. P. corylifolia L. is also a source of phyto-oestrogens because PCE contains oestrogen-like compounds such as coumarin and members of the flavonoid family.

The yeast transactivation assay and E-screen assay are routinely used for phyto-oestrogen screening, and the ER binding assay is performed to compare binding affinity for the ER.

*** P = 0·001 (ANOVA).
We evaluated the effects of PCE and bakuchiol treatment on body-weight gain, uterine weight and bone loss in ovariectomised rats. Body-weight gain is associated with metabolic abnormalities in postmenopausal women, and oestrogen treatment decreases weight gain and visceral fat development in animals and humans\(^\text{26,27}\). The PCE-supplemented groups gained significantly less weight than the OVX group and a similar amount of weight as the sham and OE groups, whereas weight gain was similar in the bakuchiol-treated groups and the OVX group. Szkudelska, Nogowski reported that genistein decreased body- and fat tissue-weight gain, and that these changes are accompanied by lower feed intake\(^\text{29}\). However, in our experiments, the feed intake did not differ significantly between the bakuchiol- and PCE-treated groups and the OVX and OE groups. The feed efficiency ratio was similar in all groups except the OVX and BH groups.

The uterotrophic effects of oestrogen treatment are undesirable in postmenopausal women because they may increase the risk of endometrial cancer\(^\text{30}\). The goal of many studies is to identify a new phyto-oestrogen as an alternative to HRT for preventing osteoporosis without causing uterine hormone stimulation. However, there is an ongoing controversy about phyto-oestrogens and their uterotrophic effects. Anderson et al.\(^\text{31}\) provided evidence that genistein treatment (0.5, 1.6 and 5.0 mg/d) did not exhibit any uterotrophic activity, but showed dosage-dependent biphasic effects on bone tissue in the ovariectomised rat model. However, Fanti et al.\(^\text{32}\) reported that higher genistein doses (50 \(\mu\)g/g body weight) caused an increase in uterine mass. Other studies with genistein and daidzein have also demonstrated weak oestrogenic effects, as reflected by changes in uterine weight\(^\text{29,32,33}\). The effect of dietary equol on uterotrophic activity is 3.5 times less than the effect of E2 treatment, and equol shows weak uterotrophic activity in mice\(^\text{37}\). In the present study, uterine weight was much lower in the OVX group with oestrogen deficiency than in the sham and E2-treated groups. Bakuchiol administration and PCE supplementation had no effect on uterine weight increase. These results suggest that bakuchiol and PCE treatment have no uterotrophic activity, despite having significant oestrogenic activity. Taken together, these data suggest that bakuchiol and PCE treatments may alleviate menopausal symptoms without increasing the risk of cancer in postmenopausal women.

Decreased plasma E2 and increased bone loss are the most prevalent symptoms in postmenopausal women. It has been well documented that isoflavone or other phyto-oestrogen supplements modulate plasma E2 and exert a protective effect on bone loss\(^\text{34}\). However, genistein has been shown to have adverse effects on tumours and on the uterus in women with postmenopausal breast cancer, despite beneficial effects on bone\(^\text{35}\). Genistein also shows both positive and negative effects on experimental endothelial dysfunction\(^\text{36}\). In addition, pomegranate extract inhibits ovariectomy-stimulated bone turnover\(^\text{37}\) and high dietary levels of soya isoflavones do not stimulate breast or uterine proliferation in postmenopausal monkeys and may contribute to an oestrogen profile associated with reduced breast cancer risk\(^\text{38}\). Our present data suggest that bakuchiol and PCE supplementation significantly increase the plasma E2 level, suggesting that bakuchiol acts as a potent phyto-oestrogen.

We found that both bakuchiol and PCE treatments in ovariectomised rats resulted in lower ALP and IP in serum, higher
Ca in serum, and increased BMD of the proximal femur. ALP is a key enzyme for bone calcification and provides an index of cell differentiation for bone formation\(^{(16)}\). Increased ALP levels indicate a positive effect on osteoblastic differentiation, particularly for ER\(_{\beta}\) and PCE treatments. Usually, osteoclasts are induced when the Ca:IP ratio increases\(^{(15)}\). In the present study, increases in serum ALP levels were effective in preventing bone loss without the need for oestrogen. Bakuchiol and PCE treatments should be effective in preventing bone loss and could be potent phyto-oestrogens and useful alternatives to HRT.

In the present study, we screened oestrogenic compounds from PCE by \textit{in vitro} assays and identified bakuchiol as the most active component. Bakuchiol showed a higher selectivity for ER\(_{\alpha}\) than for ER\(_{\beta}\), which could be related to its bone-protective properties. In our animal study, bakuchiol or PCE treatments were effective in preventing bone loss without significant uterotrophic activity in ovariectomised rats. In conclusion, bakuchiol and PCE treatments should be effective in preventing bone loss and could be potent phyto-oestrogens and useful alternatives to HRT.
