Background Inpatient mental health settings have been described as “obesogenic” environments, due to factors including psychotropic medication, high calorie food, restricted physical activity and sedentary lifestyles. No research has investigated obesity among forensic intellectual disability inpatients, despite this populations’ increased risk. Therefore, this paper aims to evaluate the prevalence and correlates of overweight and obesity on, and during admission.

Method The weight and body mass index data of 46 inpatients (15 women and 31 men) within a specialist intellectual disability forensic service was examined for the study.

Results Only six patients (13%) were a normal weight at admission, whereas 40 (87%) were overweight or obese. During their admission, 28 (61%) gained weight (average 11.8 kg), and one (2%) maintained. However, 17 patients (37%) lost weight (average 6.2 kg), though 16 remained in overweight/obese categories. There was no correlation between length of stay and weight/BMI.

Conclusions The majority of patients were overweight or obese on admission, and approximately 60% gained weight during their admission. Women appeared at greater risk of obesity. There was no relationship between length of stay and weight. This is potentially due to the high prevalence of obesity on admission and the impact of previous admissions on weight. The results highlight the need for effective weight management interventions with this population.

Introduction Serial killer’s (SK) familiar relations often present a disorganized adherence characterized by the paternal absence and the excessive maternal coldness or over-protection. This familiar diagram, joined to mistreatment situations, could generate different antisocial conducts in the child because of the vacancy of a significant strong figure.

Objectives To study, in the SK, the relation between having suffered childhood mistreatment and the sexual aggression to the victims before killing them.

Method A study is realized between the variables of childhood mistreatment and sexual aggression to the victims. The data has been extracted from 100 protocols of SK with different nationalities elaborated by the unit of analysis of criminal behavioural (University of Salamanca, Spain).

Results The results show a significant relation between both variables.

Conclusions It can be confirmed that the SK who have suffered childhood mistreatment sexually attack their victims before killing them while those who did not experiment it during their childhood do not realize that conduct.
