The present study was planned to investigate the protective effect of 10% and 20% apricot-containing feed on carbon tetrachloride (CCl4)-induced hepatic steatosis and damage. Adult male Wistar rats (n=42) were divided into six groups of seven each, as follows: control group; CCl4 group; CCl4 + 10% apricot group; CCl4 + 20% apricot group; 10% apricot group; 20% apricot group. All apricot groups were fed with 10% or 20% apricot-containing feed for 5 months. CCl4 injections were applied to the CCl4 groups at the dose of 1 mg/kg for 3 d at the end of 5 months. In the CCl4 group, vacuolated hepatocytes and hepatic necrosis were seen, especially in the centrilobular area. Hepatocytes showed an oedematous cytoplasmic matrix, large lipid globules and degenerated organelles. The area of liver injury was found significantly decreased with apricot feeding. Malondialdehyde and total hepatic levels and catalase, superoxide dismutase and glutathione peroxidase activities were significantly changed in the CCl4 group and indicated increased oxidative stress. Apricot feeding decreased this oxidative stress and ameliorated histological damage. We concluded that apricot feeding had beneficial effects on CCl4-induced liver steatosis and damage probably due to its antioxidant nutrient (β-carotene and vitamin) contents and high radical-scavenging capacity. Dietary intake of apricot can reduce the risk of liver steatosis and damage caused by free radicals.

Carbon tetrachloride: Apricots: β-Carotene: Oxidative stress

Hepatic steatosis results mainly from increased delivery of NEFA to the liver, and from a misbalance in endogenous lipid synthesis and catabolism in hepatocytes. Hepatic steatosis can lead to fatty liver disease. Non-alcoholic fatty liver disease is characterised by fatty infiltration of the liver, inflammation, hepatocellular damage and fibrosis. Non-alcoholic fatty liver disease is considered as the hepatic manifestations of the metabolic syndrome. The metabolic syndrome refers to a cluster of features including obesity, glucose intolerance, dyslipidaemia and hypertension(1-4).

Carbon tetrachloride (CCl4) is a highly toxic chemical agent which is used as an industrial solvent. CCl4 is widely used to induce hepatic steatosis and to study the effects of protective agents, especially antioxidants. The toxic effects of CCl4 on the liver have been extensively studied(3-8). Metabolic activation of CCl4 by cytochrome P450 to the free radicals, namely trichloromethyl peroxyl radicals, is reported to enhance lipid peroxidation and protein oxidation in the liver, resulting in widespread membrane damage and liver injury. Membrane damage also causes alterations in lipoprotein secretion and accumulation of lipoprotein and lipid droplets in hepatocytes(3-5).

Epidemiological observations have shown that a high intake of fruits and vegetables has health benefits against some types of cancer and cardiovascular disorders(9-11). Their health-promoting properties are due to high vitamin, phytochemical (carotenoids, flavonoids, etc) and fibre content. Vitamins and phytochemicals show antioxidant, anti-inflammatory and anti-atherogenic effects in vivo(12-14).

The dietary intake of vitamins, carotenoids and flavonoids, which are widely distributed in fruits, could be beneficial in protecting against hepatotoxicity(15-16). Apricot (Prunus armeniaca L.) is a fruit which has a high content of carotenoids, mainly β-carotene. β-Carotene is the source of provitamin A. A quantity of 250 g fresh or 30 g dried apricots provides 100 % of the recommended daily allowance of provitamin A(17). Apricot also contains vitamins C and E and Se(18). β-Carotene and vitamins C and E are well-known dietary antioxidants(19,20). Vitamins show other beneficial effects in vivo besides their antioxidant properties. Vitamin A (retinol) is the precursor of retinoids. A deficiency of this vitamin leads to night blindness(21). Vitamin C has cofactor activity for several important enzymes(22). Vitamin C is also a component of the enzyme ascorbic acid, which is involved in the synthesis of collagen and other connective tissue proteins(23).

Abbreviations: ALT, alanine amino transferase; AST, aspartate amino transferase; CAT, catalase; DPPH, 1,1-diphenyl-2-picrylhydrazyl; GSH, glutathione; GSH-Px, glutathione peroxidase; MDA, malondialdehyde; RSP, radical-scavenging power; SOD, superoxide dismutase; TGSH, total glutathione.

There are data about the beneficial effects of β-carotene and vitamins as antioxidants \(^{10,24}\), but their effects when consumed in foods are not well defined. Apricot is a stone fruit and it is widely produced in Malatya province, situated in the eastern region of Turkey. According to recent statistics, about 80% of apricot production originates from this region and 95% of this production is marketed as dried apricots \(^{25}\).

The region has about 8 million apricot trees, 17% of which are of the ‘Kabaasi’ cultivar \(^{26}\). Especially the ‘Hacihalilo glu’, ‘Cologlu’, ‘Zerdali’ and ‘Kabaasi’ cultivars have high antioxidant capacity, in vitro \(^{27}\).

In the present study, our aim was to investigate the long-term effect of apricot feeding on hepatic steatosis and damage induced by CCl\(_4\).

Experimental methods

Reduced glutathione (GSH), β-NADPH, sodium azide, 5′,5′-dithiobis(2-nitrobenzoic acid), nitroblue tetrazolium, 2-thiobarbituric acid and cytochrome c were obtained from Merck (Darmstad, Germany). All other chemicals were obtained from Sigma Chemical Co. (St Louis, MO, USA) unless otherwise stated.

Preparation of 10% and 20% apricot-containing rat pellet feed

The naturally sun-dried ‘Kabaasi’ cultivar (produce of Malatya, Turkey, obtained from Karapinar Kirlangic Village Agricultural Cooperative) was used in the present study because of its high radical-scavenging power (RSP). The rat feeds containing 10% and 20% natural dried apricots were prepared in Elazig Feed Factory (Elazig Yem Sanayii, Elazig, Turkey, obtained from Karapinar Kirlangic Village Agricultural Cooperative) was used in the present study because of its high radical-scavenging power (RSP). The rat feeds containing 10% and 20% natural dried apricots were prepared in Elazig Feed Factory (Elazig Yem Sanayii, Elazig, Turkey). The metabolic energy value was regulated to 11 095 kJ/kg (2650 kcal/kg) in the 10% and 20% apricot-containing feeds like the standard rat pellets. The composition of the feeds is presented in Table 1.

Extract preparation

Standard pellet feed, apricot-containing feeds and sun-dried apricot samples (10 g) were mixed with 90 ml ethanol (70%) and were crushed by using an Ultra-Turrax homogeniser (Ultra-Turrax, model T25; IKA-Works, Inc., Wilmington, NC, USA) at 12 000 g. The suspensions were kept in the refrigerator (+4°C) for 48 h and filtered through Whatman no. 1 filter paper. Extracts were used in the 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical-scavenging test.

1,1-Diphenyl-2-picrylhydrazyl radical-scavenging power assay

The RSP of standard pellet feed, apricot-containing feeds and dried apricot extracts were assessed by the method of Shimada et al. \(^{28}\) with slight modifications in 2 ml of reaction mixture containing 2.9 mmol DPPH (1·8 ml 1 × 10⁻⁴ m·DPPH) and 0.2 ml of extracts. In the control, ethanol (70 %) was used in place of the sample. Cuvettes were left in the dark at room temperature for 10 min and the resulting colour was measured spectrophotometrically at 520 nm against blanks. A decreasing intensity of purple colour was related to higher RSP percentage, which was calculated using the following equation:

\[
\% RSP = \left(1 - \frac{A_{S;10}}{A_{B;10}} \right) \times 100,
\]

where \(A_{S;10}\) is the absorbance of the samples and \(A_{B;10}\) is the absorbance of the blank at the 10th min of the reaction period.

Animals and experimental groups

Adult male Wistar rats (\(n = 42\)) weighing 250–350 g were provided by the Inonu University Laboratory Animals Research Centre. Animals were fed with standard rat feed and tap water ad libitum for 10 d and randomly divided into six groups of seven each, as follows: control group (308·0 (SD 22·7) g); CCl\(_4\) group (310·6 (SD 32·2) g); CCl\(_4\) + 10% apricot group (314·0 (SD 25·8) g); CCl\(_4\) + 20% apricot group (313·0 (SD 37·5) g); 10% apricot group (309·4 (SD 34·9) g); 20% apricot group (309·4 (SD 22·8) g). The experiment lasted for 5 months.

The control and CCl\(_4\) groups were fed by the standard rat pellet, the 10% apricot group and the CCl\(_4\) + 10% apricot groups were fed by 10% apricot-containing pellets, and the 20% apricot group and the CCl\(_4\) + 20% apricot groups were fed by 20% apricot-containing pellets during 5 months. The CCl\(_4\), CCl\(_4\) + 10% apricot and CCl\(_4\) + 20% apricot groups received CCl\(_4\) at 1 ml/kg (dissolved in olive oil) (Rafet Kimya, Istanbul, Turkey) subcutaneously for 3 d at

the end of the 5 months. At 2 d after the last injection all rats were killed and livers were quickly removed.

All experiments in the present study were performed in accordance with the guidelines for animal research from the National Institute of Health and approved by the Committee on Animal Research at Inonu University, Malatya (2006/003).

Determination of liver function tests
Alanine amino transferase (ALT) and aspartate amino transferase (AST) activities were measured in serum samples obtained from all groups of rats. The measurements were done in accordance with the methods of the diagnostic kits (Biolabo Reagents, Maizy, France).

Lipid peroxidation assay (malondialdehyde)
The analysis of lipid peroxidation was carried out as described (20) with a minor modification. The reaction mixture was prepared by adding 250 μl homogenate into 2 ml reaction solution (15 % trichloroacetic acid–0·375 % thiobarbituric acid–0·25 m- HCl, 1:1:1, w/v/v) and heated at 100°C for 15 min. The mixture was cooled to room temperature, centrifuged (10 000g for 10 min) and the absorbance of the supernatant fraction was recorded at 532 nm. 1,1,3,3-Tetramethoxypropane was used as a malondialdehyde (MDA) standard. MDA results were expressed as nmol/mg protein in the homogenate.

The protein content of samples was determined using the colorimetric method of Lowry et al. (30) using BSA as the standard. All analyses were performed in duplicate.

Determination of enzyme activities
Catalase assay. Catalase (CAT) activity was measured at 37°C by following the rate of disappearance of H2O2 at 240 nm (ε240 = 40/M per cm) (31). The definition of 1 unit of CAT activity is the amount of enzyme catalysing the degradation of 1 μmol H2O2/min at 37°C and specific activity corresponding to transformation of substrate (in μmol) (H2O2)/min per mg protein.

Superoxide dismutase assay. Superoxide dismutase (SOD) activity was assayed using the nitroblue tetrazolium method of Sun et al. (32). The samples were subjected to ethanol–chloroform extraction before the enzyme activity assay. Briefly, 250 μl ice-cold ethanol–chloroform mixture (62.5:37.5, v/v) was mixed thoroughly with 250 μl of sample. After vortexing for 30 s and centrifuging at 10 000g at 4°C for 30 min, the upper aqueous layer was collected. The collected supernatant fraction was diluted by a factor of 10, and 50 μl of the diluted solution was used for the assay by adding it to 2.9 ml of SOD assay reagent and 50 μl of xanthine oxidase solution (0.16 U/ml). Nitroblue tetrazolium was reduced to blue formazan by O2–, which has a strong absorbance at 560 nm. The definition of 1 unit of SOD is the amount of protein that inhibits the rate of nitroblue tetrazolium reduction by 50%. The calculated SOD activity was expressed as U/mg protein in the tissue.

Glutathione peroxidase assay. Glutathione peroxidase (GSH-Px) activity was determined in a coupled assay with glutathione reductase by measuring the rate of NADPH oxidation at 340 nm using H2O2 as the substrate (33). The enzyme reaction contained 30 mm-potassium phosphate, pH 7·0, 1 mm-EDTA, 0.2 mm-NADPH, 2 mm-GSH, 1 mm-sodium azide, 1 U glutathione reductase and 0.1 mm-H2O2.

The definition of 1 unit of GSH-Px is the amount of NADPH (μmol) disappeared/min per mg protein.

Total glutathione assay. The total glutathione (GSH) level was performed using the method of Theodorus et al. with some modifications (34). The reaction mixture contained 50 mm-sodium phosphate, 1 mm-EDTA, 0·5 mm-5′-dithio-bis(2-nitrobenzoic acid), 0·2 mm-NADPH and glutathione reductase (0·5 U/ml). Homogenate (10 μl) was added to initiate the reaction but was omitted for the control. The formation of thiop-2-nitrobenzoate was followed spectrophotometrically at 412 nm. The amount of GSH in the extract was determined as nmol/mg protein utilising a commercial GSH as the standard.

Histological examination
For light microscopic evaluation, liver samples were fixed in phosphate-buffered 10 % formalin. Paraffin-embedded specimens were cut into 5 μm thick sections and stained with Crossman’s triple staining (35,36). The livers were examined with a Leica DFC 280 light microscope by an experienced observer unaware of the animal treatment groups. The Leica Q Win Plus Image Analysis System (Leica microscope Imaging Solutions Ltd, Cambridge, UK) was used for morphometric analysis. Centrilobular necrosis areas (the areas full of vacuolated and necrotic hepatocytes) were measured in ten different fields for each section.

For transmission electron microscopic evaluation the samples were placed into 3 % glutaraldehyde buffered with 0·2 M-NAH2PO4 + NaHPO4 (pH 7·2–7·3) and post-fixed with 2 % osmium tetroxide (OsO4) and embedded in Araldite CY 212. Ultrathin sections were stained with uranyl acetate and lead citrate and examined with a Zeiss Libra 120 (Carl Zeiss NTS GmBH, Oberkochen, Germany) transmission electron microscope.

Statistical analysis
Results were expressed as arithmetic mean values and standard deviations. Results were statistically analysed by the Kruskal–Wallis H test and were considered to be significant when P<0·05. The differences between the groups were evaluated by the Mann–Whitney U test.

Results
1,1-Diphenyl-2-picrylhydrazyl radical-scavenging power assay
The DPPH RSP of the standard rat chow, the 10 % and 20 % apricot-containing rat chows and dried apricot are given in Table 2. The RSP of dried apricot and apricot-containing rat pellets were significantly higher than that of the standard rat pellets (P<0·05).
British Journal of Nutrition

apricot feeding is effectively able to inhibit lipid peroxidation that apricot feeding protected liver from the effects of CCl4. According to these results, we can say that apricot feeding protected liver from the effects of CCl4.

Liver function tests

The levels of ALT and AST in serum in all groups are presented in Table 3. ALT and AST levels were 10·3 and 52·5 IU/l in the control group, 173·4 and 302·4 IU/l in the CCl4 group, 88·2 and 159·4 IU/l in the CCl4 + 10 % apricot group and 55·8 and 177·7 IU/l in the CCl4 + 20 % apricot group, respectively. According to these results, we can say that apricot feeding protected liver from the effects of CCl4.

Lipid peroxidation and enzyme results

The levels of MDA and TSHG and the activities of CAT, SOD and GSH-Px of the liver tissue are shown in Table 4. In the CCl4 group, MDA levels were increased (P<0·05) when compared with the control group. MDA levels were decreased in the CCl4 + 10 % and CCl4 + 20 % apricot groups when compared with the CCl4 group (P<0·05). CAT, SOD and GSH-Px activities and TGSH levels were increased significantly in the CCl4 + 10 % and CCl4 + 20 % apricot groups when compared with the CCl4 group (P<0·05). These results indicate that apricot feeding is effectively able to inhibit lipid peroxidation and the production of MDA, and inhibit the need and usage of antioxidant enzymes and/or stimulate the production of antioxidant enzymes in CCl4-injured liver.

Light microscopic observations

The livers of the control, 10 % apricot and 20 % apricot groups presented normal histology (Fig. 1(a)). The liver sections of the CCl4 group showed histological alterations such as vacuolated hepatocytes and hepatic necrosis, especially in the centrilobular area. Inflammatory cell infiltration and slight fibrosis around the central vein were detected (Fig. 1(d)). In the CCl4 + 10 % apricot- and CCl4 + 20 % apricot-fed groups hepatic necrosis was rare. Vacuolated hepatocytes were seen in the centrilobular area but they were not as extensive as in the CCl4 group and their vacuoli were small (Fig. 1(e)). Inflammatory cell infiltration and fibrosis were rare. In the CCl4 + 10 % apricot and CCl4 + 20 % apricot groups, hepatocytes showed extensive mitosis (Fig. 1(f)). The histological findings of these two groups were close to each other. The morphometric analysis of the liver damage is presented in Table 5. The damaged area measurements showed that apricot feeding significantly decreased (P<0·05) centrilobular necrosis induced by CCl4.

Ultrastructural observations

The ultrastructure of hepatocytes was normal in the control, 10 % apricot and 20 % apricot groups (Fig. 2(a) and (b)). In the CCl4 group some of the hepatocytes showed large lipid globules and glycogen loss (Fig. 2(c)). Some hepatocytes showed an oedematous cytoplasmic matrix with large lipid globules, degenerated organelles and heterogeneous lysosomes. Mitochondrial changes such as swelling and cristae loss were seen (Fig. 2(d) and (e)). In both the CCl4 + 10 % apricot and the CCl4 + 20 % apricot groups, apricot feeding reduced the volume and number of the lipid globules in the hepatocytes. The organelle and cytoplasm structures were widely preserved from the effects of CCl4 (Fig. 2(f) and (g)). However, glycogen loss persisted in apricot-fed groups.

Discussion

Hepatic steatosis increases the sensitivity of the liver to secondary insults and leads to lipotoxicity. Lipotoxicity causes mitochondrial dysfunction, apoptosis, necrosis, generation of oxidative stress and inflammation(1,2). Mitochondrial impairment causes enhanced reactive nitrogen species production, initiating lipid peroxidation(1).

Lipid peroxidation and oxidative damage are well defined in CCl4 hepatotoxicity. Cytochrome P450 activates CCl4 into the trichloromethyl radical, which further converts to the peroxy radical. These locally produced free radicals cause auto-oxidation of the polyenic fatty acids present within the membrane phospholipids. As a result of oxidative lipid decomposition and organic peroxide formation, lipid peroxidation occurs. Lipid export from the hepatocytes is reduced owing to their inability to synthesize apoprotein which facilitates lipoprotein secretion. This leads to fatty liver(5). Our findings in the CCl4 group are concordant with these data. We detected hepatocellular degeneration

Fig. 1. Photomicrographs of rat livers (triple staining). In the control group (a, ×66), the liver has normal histology. In the CCl₄ group (b–d) in the centrilobular area vacuolated hepatocytes (b, ×66), hepatocyte necrosis (c, ×330), slight fibrosis and inflammatory cell infiltration (d, ×132) are seen. In the CCl₄ + 10% apricot group (e, ×66) and the CCl₄ + 20% apricot group (f, ×330) vacuolisation is lessened, vacuoli are small and prominent mitotic hepatocytes are visible (*). VC, vena centralis.
with vacuolisation and necrosis of hepatocytes which was severe in the centrilobular area. The reason of the hepatocyte vacuolisation was the lipid accumulation which was seen ultrastructurally as lipid globules in hepatocytes. Several studies have reported hepatic centrilobular steatosis and necrosis after exposure to CCl₄. The changes in organelle structure and oedematous cytoplasmic matrix in this group were probably due to the changes in membrane structure caused by lipid peroxidation. We also detected glycogen loss in hepatocytes. It is believed that high energy demand caused by lipid peroxidation.

According to epidemiological studies the regular consumption of fruits and vegetables is strongly associated with the reduced risk of developing chronic diseases. Their health-promoting properties are due to high vitamin, phytochemical and fibre content. However, the isolated single phytochemical does not exert the same beneficial health effect. It seems that combinations of phytochemicals are likely to show beneficial effects by their overlapping and complementary mechanisms. Thousands of phytochemicals are present in whole foods. Apricot is a phytochemical- and vitamin-rich fruit. The synergistic effect of these compounds could probably have played an important role in apricot’s hepatoprotective effect in the present study.

There are studies about the hepatoprotective effects of natural foods and vitamins in CCl₄-induced liver damage. We detected prominent mitosis in hepatocytes of the CCl₄ + apricot group livers. Sato et al. (27) reported similar findings in their study. They detected mitosis in hepatocytes and Kupffer cells 48 h after CCl₄ treatment in rats concomitantly administered hepatocyte growth-promoting factor. Liver has a high regeneration capacity and different cytokines, complete mitogens and co-mitogens are involved in regeneration (48). We detected regenerative effect of apricot in CCl₄-induced liver damage. However, it is not possible to discuss the reasons of the mitosis induction with apricot feeding with the present findings. This issue needs further investigation.

In the present study we used two different feeds of 10 % and 20 % apricot concentration in order to compare their effects. The RSP of the dried apricot and apricot-containing feeds were analysed. The dried ‘Kabasai’ apricot showed the highest RSP. Guclu et al. (27) reported that the ‘Kabasai’ cultivar has a high antioxidant capacity in vitro. Apricot is a fruit which has a high β-carotene content. Carotenoids are naturally occurring pigments in plants that are involved in light-harvesting reactions and protection of plant organelles against singlet oxygen-induced damage. Martin et al. (42) reported that β-carotene protected HepG2 human liver cells against oxidant-mediated changes in plasma membrane integrity. Carotenoids have singlet oxygen and peroxo radical-quenching properties because of their long chain of conjugated double bonds. β-Carotene may have additive benefits due to its ability to be converted to vitamin A. β-Carotene is the major plant source of vitamin A (10,43). However, high-dose β-carotene supplementation may show pro-oxidative properties. Under heavy oxidative stress β-carotene and other carotenoids are oxidatively degraded leading to the formation of high amounts of breakdown products with pro-oxidant properties (44). These products may exert harmful effects. There are studies about the possible adverse effects of β-carotene on the incidence of lung cancer in heavy smokers (19,45).

Apricot also contains vitamins C and E and Se (18). Vitamin C is considered to be one of the most powerful, least toxic natural antioxidants. It is water soluble and has cofactor activity (19). It is an essential cofactor in the hydroxylation of procollagen chains during collagen synthesis (21). Vitamin E and Se also have antioxidant properties (22,23). We fed rats with 10 % and 20 % apricot-containing feed for 5 months before CCl₄ exposure. These feeds showed protective effects in CCl₄-induced liver injury. Apricot feeding reduced centrilobular necrosis area and preserved hepatocyte ultrastructure. ALT, AST and MDA levels decreased, and antioxidant enzyme activities increased significantly (P < 0.05) when compared with the CCl₄ group. These results indicated that apricot feeding prevented lipid peroxidation and decreased oxidative stress.

† Mean value was significantly decreased compared with that of the CCl₄ group (P<0.05).
feeds did not show significant differences from each other. Some studies showed that the DPPH-scavenging activity of nutrients reaches a plateau at a constant concentration and beyond this concentration the scavenging effect became almost stable\(^{(49,50)}\). We believe that the 20% apricot-containing feed’s RSP is probably at the plateau level. Further \textit{in vitro} studies with different concentrations of apricot-containing feeds are needed for accurate results. The histological and biochemical findings were also similar in both apricot-fed groups. Only ALT levels showed significant difference between the CCl\(_4\) + 10% and the CCl\(_4\) + 20% apricot groups. According to the lipid peroxidation assay (MDA), antioxidant enzymes and histopathological findings, 20% apricot did not improve the effect of 10% apricot any further. These \textit{in vivo} findings are concordant with the \textit{in vitro} RSP results. The improved ALT levels of the 20% apricot-containing feed could be due to non-antioxidant effects of apricot.

We conclude that long-term apricot feeding shows beneficial effects on CCl\(_4\)-induced liver steatosis and damage in rats because of its high radical-scavenging capacity. Its effect occurred probably due to its high phytochemical and vitamin content. It is possible to say that apricot as a natural food could have beneficial effects on non-alcoholic hepatic steatosis.

**Fig. 2.** Electron photomicrographs of rat livers. In the control group (a, \(\times\) 8000) and the 10% apricot group (b, \(\times\) 12500), hepatocytes show normal ultrastructure. In the CCl\(_4\) group, glycogen loss, large lipid globules (*) (c, \(\times\) 6300), oedematous cytoplasmic matrix, degenerated organelles, swollen mitochondria with cristae loss and heterogeneous lysosomes (d, \(\times\) 12500; e, \(\times\) 16000) are seen. In the CCl\(_4\) + 10% apricot group (f, \(\times\) 8000) and the CCl\(_4\) + 20% apricot group (g, \(\times\) 8000), glycogen loss persists in hepatocytes, but lipid globules are small and few.
