Cholesteatoma accompanied abnormal ossification: Report of two cases

Presenting Author: Yuko Hata1, Taeko Okuno1, Kazumi Ichinose2, Youko Yamazaki1

1Mitsui Memorial Hospital, 2Tokyo Woman’s Medical University

Learning Objectives: Case study.

It is well known the cholesteatoma causes bone erosion and destruction of ossicular chain. We experienced two cases of cholesteatoma accompanied by abnormal ossification around ossicles which showed fixation to the wall of antrum or bony wall of middle cranial fossa. Case 1 is a 39-year-old man. He visited our hospital complained hearing loss of his left ear about one year ago. He also complained otorrhea of left side six months ago, cured spontaneously. 10 years ago he had visited our hospital for his right ear surgery, then an otomicroscopic examination of his left ear showed only dry small retraction pocket. But this time the retraction pocket of his left ear had been enlarged. Computed tomography scanning (CT) revealed deformity of ossicles. An operation of his left ear was performed. Abnormal ossification was seen around malleus head and Incus body and fixed the wall of antrum. Isolated cholesteatoma was existed behind the malleus head. Case 2 is a 45-years-old woman. At the age of 23, her left ear had been operated for cholesteatoma in our hospital. 8 years later she visited our hospital for his right otalgia. An otomicroscopic examination of her right ear revealed the retraction pocket with large squamous debris. By conservative treatment her otalgia was cured and the retraction pocket was cleaned. CT revealed only small soft tissue in attic. At this time the age of 45, the debris of his left ear had been enlarged. Computed tomography scanning (CT) revealed deformity of ossicles. An operation of her right ear was performed. Ossicles fixed wall of antrum and isolated cholesteatoma by the abnormal ossification was found. It will be necessary to take into consideration of the existence of isolated cholesteatoma by abnormal ossification.

Simultaneous cochlear implantation and labyrinthectomy for advanced Ménière’s disease

Presenting Author: Rebecca Heywood

Rebecca Heywood1, Marcus Atlas2

1Ng Teng Fong General Hospital, 2Ear Science Institute Australia

Learning objectives:

1. Understand the challenges in managing intractable vertigo in Ménière’s disease.
2. Review the literature on cochlear implantation outcomes in Ménière’s disease.
3. Learn about simultaneous labyrinthectomy and cochlear implantation as an emerging technique in the management of Ménière’s patients with intractable vertigo.

Introduction: Patients with Ménière’s disease can develop unaidable sensorineural hearing loss. Cochlear implantation
Magnetic Resonance Imaging surveillance after subtotal petrosectomy and blind sac closure: A review of radiological findings and long term follow up

Presenting Author: Rebecca Heywood

Rebecca Heywood1, Rudolf Boeddinghaus2, Katherine Pollaers3, Peter Friedland3, Marcus Atlas4
1Ng Teng Fong General Hospital, 2Ear Science Radiological Clinic, 3Sir Charles Gairdner Hospital, 4Ear Science Institute Australia

Learning objectives:
1. Understand the MRI features of the temporal bone post SP BSC.
2. Understand more about the behaviour of the temporal bone when it has been isolated from the external environment.
3. Understand the role of MRI in surveillance of the temporal bone post SP BSC.

Introduction: Long term follow up is recommended following subtotal petrosectomy (SP) with cavity obliteration and blind sac closure (BSC) of the external auditory canal to detect recurrent or iatrogenic cholesteatoma and chronic otitis media (COM). Follow up has historically been a challenge both clinically and radiologically. Recent advances in MRI have transformed our ability to survey patients post SP BSC. The objectives of this study were to: i. Characterise the MRI features post SP BSC; ii. Assess the behaviour of the temporal bone and disease persistence/progression post SP BSC; iii. Classify the radiological features and define their consequences for clinical care.

Methods: Retrospective case note review was performed in a tertiary referral hospital of 23 patients who underwent SP BSC between November 2004 and October 2013. MRI surveillance was carried out over a mean follow up period of 48 months (range 14–116). MRI features over time were compared to clinical course and surgical findings.

Results: Otitis media with effusion is a common finding in the unventilated temporal bone but appears to have little if any clinical consequence. Revision surgery was performed on clinical grounds in four patients (17%) and concerning imaging features but no clinical concerns in three patients (13%). Radiological findings correlated with operative and histological findings for cholesterol granuloma and mucosal COM but there was discrepancy in the diagnosis of cholesteatoma.

Conclusions: The MRI features of the temporal bone post SP BSC are described. A grading system for radiological findings is proposed to guide surveillance and possible further surgical intervention.

Learning objectives:
1. Understand the challenges related to hearing health and cognitive decline in seniors facing a small country that has undergone rapid development over the last 50 years.
2. Identify ways that may start to address these through education and research.

Introduction: The burden of dementia continues to rise worldwide. Hearing loss has been independently associated with accelerated cognitive decline and identified as an independent risk factor for all-cause dementia. Singapore is a small country facing a rapidly ageing population. This study aims to review the current status of hearing health and cognitive decline in seniors in Singapore.

Methods: A literature search of articles published in English was conducted based on PRISMA guidelines.

Results: The prevalence of dementia is estimated to be 10% in those ≥60 years and increases with age. Interethinic
