Gastric bypass surgery (GB) is a safe, effective treatment for morbid obesity¹. Aside from reduced energy consumption, patients report changes in food preferences and appetite that may contribute to weight loss post-surgery²,³. Food preferences can be separated into two constructs; ‘liking’ (pleasure) and ‘wanting’ (motivation/desire to eat)⁴ which may be influenced by physiological and psychological changes post-surgery. The aim of this study was to investigate changes in food preferences (‘liking’ and ‘wanting’) in GB patients from pre- to post-surgery, compared to weight-stable controls.

Nineteen patients (45±12.5 years, Body Mass Index (BMI): 45±6.4 kg/m²) and sixteen time-matched controls (44±7±15.6 years, BMI: 25±4.4 kg/m²) completed the computer-based Leeds Food Preference Questionnaire, which assesses preferences for sweet/savoury foods and low-fat/high-fat foods⁵ at baseline (1-month pre-surgery) and 3-months post-surgery. Explicit liking and wanting (conscious hedonic feelings/desire to consume) were measured using Visual Analogue Scales, whilst implicit wanting (unconscious motivational expression) was measured using food selection and reaction times in a forced-choice task.

There were no significant differences in food preferences between patients and controls at baseline. BMI for controls remained stable (+0.1±1.3 kg/m², p = 0.73), whilst BMI in patients significantly decreased (−8.3±2.7 kg/m², p = <0.01). GB patients expressed a significant decrease in the explicit liking (F(1,33) = 10.42, p = 0.03), explicit wanting (F(1,33) = 5.76, p = 0.02) and implicit wanting (F(1,33) = 4.92, p = 0.03) for sweet foods after surgery. However, there were no significant changes in preferences for high-fat foods in patients from pre to post-surgery. There were no significant changes in preferences for controls for sweet or high-fat foods.

In conclusion, patients express a significant decrease in preferences for sweet foods post-surgery. As changes in implicit unconscious motivational expression of food preferences may be more predictive of actual food consumption⁶ these findings highlight a possible mechanism responsible for the success of GB as an obesity treatment.
