Blood Flow Differences Between Leuko-araiosis With and Without Lacunar Infarction

Minoru Oishi, Yoko Mochizuki and Toshiaki Takasu

ABSTRACT: Background: The present study was designed to find the differences in regional cerebral blood flow and cerebrovascular acetazolamide reactivity between leuko-araiosis with and without lacunar infarction. Methods: Fifteen cases of leuko-araiosis with lacunar infarction, 15 cases of leuko-araiosis without lacunar infarction and 15 age-matched controls in which leuko-araiosis and cerebrovascular diseases are absent (control group) were studied. The regional cerebral blood flow was measured using the stable xenon computed tomography method before and 20 minutes after intravenous injection of 17 mg/kg acetazolamide. Results: The blood flows in the leuko-araiosis area and the lacunar area were significantly lower than the blood flow in the cerebral white matter. The blood flows in the cerebral cortex and the cerebral white matter were significantly lower in the leuko-araiosis with lacunar infarction group than in the leuko-araiosis without lacunar infarction group and the control group. The cerebrovascular acetazolamide reactivity in the leuko-araiosis area and the lacunar area was significantly lower than that in the cerebral white matter. The cerebrovascular acetazolamide reactivity in the cerebral cortex and the cerebral white matter was significantly lower in the leuko-araiosis with lacunar infarction group than in the leuko-araiosis without lacunar infarction group and the control group. Conclusions: The degree of arteriolosclerosis is considered to be more severe and the rate of association of hypertension was higher in leuko-araiosis with lacunar infarction than in leuko-araiosis without lacunar infarction.

RéSUMÉ: Différence dans le débit sanguin dans la leucoaraïose avec et sans infarcissement lacunaire. Introduction: Cette étude a été conçue dans le but de mettre en évidence les différences dans le débit sanguin cérébral régional et dans la réactivité à l’acétylazolamide dans la leucoaraïose avec et sans infarcissement lacunaire. Méthodes: Nous avons étudié 15 cas de leucoaraïose avec infarcissement lacunaire, 15 cas de leucoaraïose sans infarcissement lacunaire et 15 cas contrôles appariés pour l’âge qui ne présentaient pas de leucoaraïose ou de maladie vasculaire cérébrale (groupe contrôle). Nous avons mesuré le débit sanguin cérébral régional au moyen de la tomodensitométrie au xénon stable avant injection intraveineuse de 17 mg/kg d’acétylazolamide et 20 minutes après. Résultats: Les débits sanguins dans les zones de leucoaraïose et d’infarcissement lacunaire étaient significativement plus faibles que les débits sanguins dans la substance blanche. Les débits sanguins dans le cortex et dans la substance blanche étaient significativement plus faibles dans le groupe avec leucoaraïose et infarctus lacunaire que dans le groupe avec leucoaraïose sans infarctus lacunaire et dans le groupe contrôle. La réactivité vasculaire cérébrale à l’acétylazolamide dans les zones de leucoaraïose et dans les zones lacunaires était significativement plus faible que dans la substance blanche. La réactivité vasculaire cérébrale à l’acétylazolamide dans le cortex et dans la substance blanche était significativement plus faible dans le groupe avec leucoaraïose avec infarctus lacunaire que dans le groupe avec leucoaraïose sans infarctus lacunaire et dans le groupe contrôle. Conclusion: Nous avons observé une artériosclérose plus sévère et une prévalence plus élevée d’hypertension dans la leucoaraïose avec infarctus lacunaire que dans la leucoaraïose sans infarctus lacunaire.

between leuko-araiosis with lacunar infarction and leuko-araiosis without lacunar infarction. Therefore, we measured regional cerebral blood flow before and after intravenous injection of acetazolamide in patients with leuko-araiosis.

**Subjects and Methods**

Fifteen cases of leuko-araiosis with lacunar infarction, 15 cases of leuko-araiosis without lacunar infarction and 15 age-matched controls in which leuko-araiosis and cerebrovascular diseases are absent (control group) were studied with their informed consent. These patients were prospectively enrolled into the study. The patients with leuko-araiosis were admitted to our hospital and head computed tomography (CT), head magnetic resonance imaging (MRI), echocardiography and blood viscosity were studied on the patients. Subcortical cystic infarctions with a diameter of less than 1.5 cm were diagnosed as lacunar infarction.14 The patients with hydrocephalus, leukodystrophy and lacunar infarction in the acute stage were excluded from this study. Medications such as cerebral vasodilators which influence cerebral blood flow were discontinued 2 weeks prior to the cerebral blood flow examination. Fifteen cases in each group were selected by the order of admission date. Table 1 shows the subjects’ characteristics in the 3 groups.

The degree of white matter lesions was graded using the method of Kobari et al. and the degree of white matter lesions in anterior and posterior regions was graded using the method of Van Swieten et al.16

The regional cerebral blood flow was measured using the stable xenon CT method.7,18 The basal ganglia section and the lateral ventricle section parallel to the orbito-meatal line were studied. The subjects inhaled room air followed by a mixture of 30% xenon and 50% oxygen for 3 minutes. Serial scanning was performed once before xenon inhalation, three times in the washin process and five times in the washout process of 5 minutes. The serial scanning program consisted of a total of 18 scans consisting of 9 serial scans on each section. The xenon concentration in the end-tidal expired gas was continuously recorded by the thermoconductivity method. We used the xenon delivery and analysis system (AZ-7000 model, Anzai Sogyo, Tokyo, Japan) and the CT equipment (PreSage, Yokogawa Medical Systems, Tokyo, Japan).

Regional cerebral blood flows were measured in the leuko-araiosis area, in the lacunar infarction area, and in the cerebral cortex and cerebral white matter where the influence of the leuko-araiosis and the lacunar infarction was considered to be little. Round region of interest (ROI) with a diameter of 7 mm was used and the ROI was placed in the center of each leuko-araiosis area in bilateral anterior and posterior regions. The leuko-araiosis area blood flow was calculated as the average of the blood flows in the 4 leuko-araiosis areas. Out of 15 cases of leuko-araiosis with lacunar infarction, 6 had lacunar infarction in the thalamus, 5 had lacunar infarction in the frontal white matter and 4 had multiple lacunar infarctions. The lacunar infarction area blood flow was measured placing the ROI in the lacunar area. In bilateral frontal lobes, parietal lobes, temporal lobes and occipital lobes, the ROI was placed in the area where leuko-araiosis and lacunar infarction were not adjacent and direct nerve fiber connection with the lacunar infarction area.

The cerebral cortex blood flow and cerebral white matter blood flow were calculated as the average of the blood flows in the 8 areas.

Arterial CO₂ tension was measured before the examination, 20 minutes after intravenous injection of acetazolamide and after the examination.

Statistical analysis was performed using Mann-Whitney’s U tests for comparison of the cerebral blood flows and using Fisher’s exact probability tests for comparison of risk factors among the 3 groups.

**Results**

Figure 1 shows head magnetic resonance imaging and CT scan in a case of leuko-araiosis with lacunar infarction. Figure 2 shows head magnetic resonance imaging and CT scan in a case of leuko-araiosis without lacunar infarction. The degree of leuko-araiosis did not show any significant difference between the leuko-araiosis with lacunar infarction group and the leuko-araiosis without lacunar infarction group (Table 2). The rate of association of hypertension was significantly higher in the leuko-araiosis with lacunar infarction group than in the leuko-araiosis without lacunar infarction group and the control group (Table 1).

Figure 3 shows the actual record of xenon CT before and after intravenous injection of acetazolamide. Table 2 shows the mean and standard deviation of the regional cerebral blood flows. The blood flows in the leuko-araiosis area and the lacunar area were significantly lower than the blood flow in the cerebral cortex.

white matter. The blood flows in the cerebral cortex and the cerebral white matter where the influence of the leuko-araiosis and the lacunar infarction was considered to be little were significantly lower in the leuko-araiosis with lacunar infarction group than in the leuko-araiosis without lacunar infarction group and the control group. The cerebrovascular acetazolamide reactivity in the leuko-araiosis area and the lacunar area was significantly lower than that in the cerebral white matter. The cerebrovascular acetazolamide reactivity in the cerebral cortex and the cerebral white matter where the influence of the leuko-araiosis and the lacunar infarction was considered to be little was significantly lower in the leuko-araiosis with lacunar infarction group than in the leuko-araiosis without lacunar infarction group and the control group (Table 3).

Arterial CO₂ tension did not show any significant difference between before and after the examination and between before and 20 minutes after the intravenous injection of acetazolamide.

**DISCUSSION**

Leuko-araiosis has many causes, but the common causes are considered to be arteriolosclerosis and normal aging. Cerebral blood flow has been reported to be decreased in leuko-araiosis; however, leuko-araiosis is frequently associated with lacunar infarction and mean regional cerebral blood flow has been reported to be decreased in lacunar infarction. Because the decreased cerebral blood flow in leuko-araiosis may be related to lacunar infarction, we compared the cerebral blood flow between the leuko-araiosis with lacunar infarction group and the leuko-araiosis without lacunar infarction group.

Acetazolamide is considered to dilate the cerebral arterioles by inhibiting the carbonic anhydrase in the red blood cells and increasing CO₂ in the arterioles. Acetazolamide has been used for examining cerebrovascular dilatory reserve capacity. Yamamoto et al. reported that cerebrovascular CO₂ reactivity was mildly decreased in arteriosclerosis due to normal aging, moderately decreased in normal persons with risk factors of cerebral arteriosclerosis, and markedly decreased in cerebrovascular diseases and that CO₂ inhalation is a useful screening examination in cerebral arteriosclerosis. Acetazolamide has a cerebrovascular dilating effect similar to CO₂ and decreased acetazolamide reactivity is considered to suggest arteriosclerosis.

In the present study, cerebrovascular acetazolamide reactivity was decreased in the leuko-araiosis area. This suggests that cerebrovascular dilatory reserve capacity is decreased in the leuko-araiosis area. The blood flow and acetazolamide reactivity in the cerebral cortex were significantly lower in the leuko-araiosis with lacunar infarction group than in the leuko-araiosis without lacunar infarction group in the present study. Figure 3: Actual record of xenon computed tomography before and after intravenous injection of acetazolamide. A: leuko-araiosis with lacunar infarction, B: leuko-araiosis without lacunar infarction, C: control. Before the intravenous injection of acetazolamide, the cerebral blood flow is lower in A than in B and C. After the intravenous injection of acetazolamide, the increase rate in cerebral blood flow is less in A than in B and C.
suggested that the degree of arteriosclerosis may be more severe in leukoaraiosis with lacunar infarction than in leukoaraiosis without lacunar infarction. The leukoaraiosis may be divided into leukoaraiosis with lacunar infarction, in which arteriosclerosis is the commonest cause, and leukoaraiosis without lacunar infarction, in which axonal degeneration associated with normal aging is the commonest cause.

The rate of association of hypertension was higher in the leukoaraiosis with lacunar infarction group than in the leukoaraiosis without lacunar infarction and leukoaraiosis without lacunar infarction. The leukoaraiosis may be associated with normal aging is the commonest cause.
