Two-dimensional layered materials (2DLMs) with intriguing properties are hot topics of current interest, which have been extensively explored in photocatalyst, photocathodes, sensors and nanoelectronic devices et al [1-2]. They are usually featured by a single atom- thick or polyhedral-thick atomic layers with covalent or ionic bonding within each layer and van der Waals bonding. As such, the weak van der Waals interaction enables the possibilities of integrating 2DLMs with various nanoscale materials to create diverse van der Waals heterostructures (vdWHs) with functions that were not previously possible or tailoring their electronic and optoelectronic properties for functional devices [3].

The bismuth oxychloride (BiOCl) is a typical 2DLM featured with layered structure of \([\text{Cl-Bi-O-Bi-Cl}]\) slices stacking along the [001] direction by the van der Waals interaction through chlorine atoms [4]. To widen the application and tailor the conductor properties of 2DLM BiOCl, phases and polymorphs which can complement or enhance properties of this unique 2D ternary semiconducting system are explored in the Bi-O-Cl system, such as Bi\(_3\)OCl, Bi\(_{12}\)O\(_{15}\)C\(_6\), Bi\(_{24}\)O\(_{31}\)Cl\(_{10}\) [5, 6]. The previous studies show that Bi\(_3\)OCl could be excited by the visible light and the photocurrent density is 15 \(\mu\text{A/cm}^2\), while the Bi\(_{24}\)O\(_{31}\)Cl\(_{10}\) with narrowed band gap of 2.8 eV and the power conversion efficiency could be 1.5\%. Myung et al. reported that the intrinsic conductivity switches from p-type to n-type as the BiOCl transferred to an oxygen-rich Bi\(_{12}\)O\(_{15}\)C\(_6\) phase, and the photoconductivity increase of 80 times [7]. More interesting, a periodic super lattice structure appeared resulting from the atomic rearrangement of the Bi\(^{3+}\), O\(^2-\) and Cl\(^-\) ions. It is thereby expected that the super lattice periodicity and the resulting properties can be tailored by control of the stoichiometry in the BiOCl system.

In the present study, the in-situ fabrication of Bi\(_{12}\)O\(_{15}\)C\(_6\) and Bi\(_{24}\)O\(_{31}\)Cl\(_{10}\) super lattice structure are achieved by in-situ annealing BiOCl. As shown in Figure 1, the lattice spacing is determined to be 0.354 nm, which corresponds to the (206) crystal plane in Bi\(_{24}\)O\(_{31}\)Cl\(_{10}\), as highlighted in Figure 1a. Due to the different ratio of Bi/O/Cl atoms, the Fast Fourier Transform (FFT) patterns of A, B, C (marked in Figure 1a) show an evolution process of super lattice structure with a tunable period. Different long period structures are significantly observed both in the FFT patterns (Figure 1 e-g) and the corresponding images (Figure 1 b-d).
