Mental health problems: journey from Baghdad to Europe

Yasir Abbasi¹ MRCpsych and Adel Omrani² MD BA

This article looks at the evidence that not only did mental health problems affect people in the past, but that the physicians of past eras made numerous attempts to understand, classify and treat mental illness. Our aim is to show the strong scientific reasoning during the medieval era, in the Islamic world in particular, and how the complexities encountered by physicians centuries ago still haunt psychiatrists today.

Leave aside what confuses common idiots, namely [the idea] that one can hit on [the right treatment] by experience [ra'iyah] without any reference to [scientific] knowledge [ilm]. For such a thing does not exist, even if one were the oldest person, because the benefit which one derives from an appropriate treatment [in such a case] is merely the result of good luck. (Abu Bakr al-Razi [died circa 925], Muslim physician and philosopher, on evidence-based practice; see Ahlilq al-tabib, 1977, pp. 77–78)

Although some Muslim scholars have been recognised in the West for their contributions to science, many have been forgotten. Others are remembered by their Greek names. It has been claimed that descriptions of schizophrenia-like disorders were uncommon before the beginning of the 19th century in the Western world. But there are numerous cases of various mental health problems reported during the medieval Islamic era and they highlight the difficulty physicians faced in managing these conditions.

Islamic culture flourished during the medieval period (from the 7th to the 15th century). Under the aegis of the Muslim emperors, not only Muslim, but also Christian, Jewish and other scientists prospered, whether or not they were Arab. They drew on ancient Greek physicians such as Hippocrates, Rufus of Ephesus and Galen (Morgan, 2007, pp. xvi–xvii). And their work had a profound effect on European medicine, as works by Johannitius (Hunain ibn Ishaq), Avicenna (Ibn Sina) and Avemroes (Ibn Rushd) were translated into Latin and became the core curriculum in the nascent universities of Europe. In this way, a constant interchange of ideas took place between the different shores of the Mediterranean (Pormann, 2008a, pp. 179–196). The knowledge of previous civilisations was thus not just transmitted to another culture, but constituted the basis for innovation and change.

The creation of dedicated hospitals and medical schools

In the medieval Arab world, hospitals were generally called bimaristan. The word is of Persian origin, bimar meaning ‘illness’ or ‘disease’ and stan ‘location’ or ‘place’. They not only cared for people who were ill but also became important centres for medical instruction, asylums for people with a mental illness (preceding Europe by over 500 years), retirement homes (meeting the basic maintenance needs of elderly and infirm people who lacked family support) and institutes for medical research (Pormann & Savage-Smith, 2006, pp. 100–101).

When the new Abbasi dynasty ousted the previous Umayyad dynasty in the 750s AD, the capital moved from Damascus to Baghdad. Professor Peter Pormann (2008b) writes:

This city witnessed the foundation of the first hospital in the modern sense, that is to say institutions which were secular in orientation and open to a wide public irrespective of their creed; in which both poor and powerful sought treatment; and where elite physicians not only looked after the patients, but also carried out research and trained the next generation of practitioners. These hospitals also developed important facilities for treating the mentally ill.

Affective disorders

Depression and melancholy

There is no evidence that the mindset of medieval Islamic physicians was comparable to our modern nosology. The concept of melancholy was greatly influenced by the works of Rufus, who theorised in terms of vapours, humoral imbalance and excess of black bile.

Ishaq Ibn Imran (died AD 903) explains that in the case of hypochondriac melancholy (Pormann 2008a, citing Garbers, 1977, p. 19), vapours rise from the stomach into the brain, where they damage the cognitive faculties. Sourcing his hypothesis on ideas by Galen, Ibn Imran divides melancholy in the hypochondriac and brain variety. The latter is further subdivided into four varieties, which broadly reflects how we currently categorise mental disorders: brain fever (organic causes, e.g. encephalitis); stupidity (intellectual disability); animal rage (manic or psychotic episode); and intense mood swings (bipolar-type illness).

The Jewish physician Ibn Maimun (Maimonides, died AD 1204) treated the Egyptian Sultan al-Afdal (son of Saladdin), who suffered from melancholy (Malinkhuliy). He gives an account in his ‘medical swansong’, where he describes the following symptoms of the sultan: ‘he also mentions the occasional occurrence of melancholy, evil thoughts, desire for solitude and foreboding of death’ (Pormann, 2008a). Hence Ibn Maimun possibly describes low mood, negative cognitions,
demotivation and reclusiveness, followed by suicidal ideation.

Ibn Miskawaih (died AD 1030), a neo-platonic philosopher, when critically appraising Rufus’s statement that ‘those who devote too much thinking about a certain science end up suffering from melancholy’, concluded that not all acts of thinking, especially not the kind of thought which results in the knowledge of the forms (Pormann, 2008a), are bad. Only engaging excessively in mental activities leads to melancholy.

Elated mood or mania
Ibn Sina states in one of his letters:

By this [cure], I have already treated people of the same station as kings who suffered from difficult melancholy which turns into elation that is a lion-like madness [junun sab’i]. (Pormann, 2008a, citing a translation by Bar-Sela et al, 1964, p. 36)

Al-Razi, in a chapter entitled ‘On melancholy and other kinds of madness’ of his Book of Experiences (Kitab al-Tijarih), describes two interesting case studies (Pormann, 2008a), one of a young man who ‘plucked his beard and showed his anger by tearing out clay from the wall’, and another of a woman who spoke in a confused way, laughed excessively and had a red face.

He also differentiated between melancholia and madness (junun, possibly psychosis), where the sufferer of the latter experienced loss of reason and the former did not.

Psychosis
Physicians have described psychosis-like illness in their essays and case histories. Ishaq Ibn Imran, in his Essay on Melancholy (Maqala fi l-Malikhuliya), describes a patient with low mood and symptoms such as foolish acts, fear, delusions (waswas) and hallucinations (Youssef & Youssef, 1996).

The most celebrated medieval medical encyclopaedia written by a physician is Ibn Sina’s Canon of Medicine (al-Qanun fi l-tibb). He defined junun (madness) as an illness where reality is replaced by fantasy; he thought that the origin of such illnesses was from the middle part of the brain (Youssef & Youssef, 1996).

Al-Masudi (died AD 956) described the condition of a king, Al-Mutadid, who experienced loss of reason and other kinds of madness (junun), describes two interesting case studies (Pormann, 2008a), one of a young man who ‘plucked his beard and showed his anger by tearing out clay from the wall’, and another of a woman who spoke in a confused way, laughed excessively and had a red face.

Al-Razi was the first ever to postulate the existence of a form of melancholy that does not involve any humoral alteration. Such sine materia psychogenic melancholy should not be treated medically but rather receive psychological treatment.

Abu Zayd Al-Balkhi (died AD 934) asserted that the mind and body are interconnected (ishtibak) and that an imbalance of body and soul can affect the person in different ways (Haque, 2004).

Al-Tabari (died AD 870), in his ground breaking book The Paradise of Wisdom (Firdaws al-Hikma), explained that certain patients suffering from melancholia might benefit from talking to a witty physician who could build good rapport and trust (Haque, 2004).

Ibn Maimun also advocated ‘psychic’ remedies, such as listening to music, because they can provide calm and rest from anxieties and worries (Pormann, 2008b).

Conclusion
We need to revisit the origins of psychiatry and rediscover its history, so that we are able to comprehend it better and give due credit to all scientists, physicians, philosophers and thinkers lost in history.

References

Al-Razi also describes people who abandoned sexual activity because of constant tension of the penis accompanied by pain and spasm.

A Christian author of Greek origin, Qusta Ibn Luqa (died AD 912) said that women also suffered from not having sex (Pormann, 2009) and described them as being afflicted by the ‘suffocation of the womb’ (ikhinaq al-rahim) and apnoea (butlan al-nafas). It seems to be the equivalent of what the Greeks called ‘hysteria’, a term which also has its origins in the word for ‘womb’ (in Greek, hystera meant the uterus).

Psychology, psychotherapy and other therapies
Al-Razi was the first ever to postulate the existence of a form of melancholy that does not involve any humoral alteration. Such sine materia psychogenic melancholy should not be treated medically but rather receive psychological treatment.

Abu Zayd Al-Balkhi (died AD 934) asserted that the mind and body are interconnected (ishtibak) and that an imbalance of body and soul can affect the person in different ways (Haque, 2004).

Al-Tabari (died AD 870), in his ground breaking book The Paradise of Wisdom (Firdaws al-Hikma), explained that certain patients suffering from melancholia might benefit from talking to a witty physician who could build good rapport and trust (Haque, 2004).

Ibn Maimun also advocated ‘psychic’ remedies, such as listening to music, because they can provide calm and rest from anxieties and worries (Pormann, 2008b).

Conclusion
We need to revisit the origins of psychiatry and rediscover its history, so that we are able to comprehend it better and give due credit to all scientists, physicians, philosophers and thinkers lost in history.
